MIMO Energy Harvesting in Full-Duplex Multi-user Networks

H. H. M. Tam, H. D. Tuan, A. A. Nasir, T. Q. Duong and H. V. Poor

Abstract—The paper aims at the efficient design of precoding matrices for the sum throughput maximization under throughput QoS constraints and energy harvesting (EH) constraints for energy-constrained devices in a full-duplex (FD) multicell multi-user multiple-input-multiple-output (MU-MIMO) network. Both time splitting (TS) and power splitting (PS) are considered to ensure practical EH and information decoding (ID). These problems are quite complex due to highly non-concave objectives and nonconvex constraints. Especially with TS, which is implementation-wise quite simple, the problem is even more challenging because time splitting variable is not only coupled with the downlink (DL) throughput function but also coupled with the self-interference (SI) in the uplink (UL) throughput function. New path-following algorithms are developed for their solutions, which just require a single convex quadratic program for each iteration and ensure fast convergence too. Finally, the FD EH maximization problem under throughput QoS constraints in TS is also considered. The performance of the proposed algorithms is also compared with that of the modified problems assuming half-duplex systems. In the end, the merit of the proposed algorithms is shown through extensive simulations.

Index Terms—Full-duplexing transceiver, energy harvesting, information precoder, energy precoder, path-following algorithm, matrix inequality

I. INTRODUCTION

Recently, wireless energy harvesting (i.e. energy constrained devices scavenge energy from the surrounding RF signals) is gaining more and more attraction from both industry and academia [1], [2]. Since the amount of energy opportunistically harvested from the ambient/natural energy sources is uncertain and cannot be controlled, base stations (BSs) in small-cell networks can be configured to become dedicated and reliable wireless energy sources [3]. The small cell size not only gives the benefit of efficient resource reuse across a geographic area [4] but also provides an adequate amount of RF energy to battery powered user equipments (UEs) for practical applications [1], [2], [5] due to the close BS-UE proximity. In order to transfer both energy and information by the same communication channel, UEs are equipped with both information decoding receiver and energy harvesting receiver. Since the received signal cannot be used for energy harvesting after being decoded, there are two available implementations for wireless energy harvesting and information decoding: (i) receive power splitting in which a receiver splits the received signal into two streams of different power for decoding information and harvesting energy separately and (ii) transmit time splitting to enable the receiver to decode information for a portion of a time frame and harvest energy for the rest. Beamforming can be applied to focus the RF signal to energy harvesting receiver or enhance throughput at information decoding receiver [5].

Most of the previous works (see e.g. [6], [7] and references therein) only focus on beamforming power optimization subject to ID throughput and EH constraints with PS in multi-input single-output (MISO) networks. The ID throughput constraints are equivalent to signal-to-interference-plus-noise ratio (SINR) constraints, which are indefinite quadratic in beamforming vectors. The harvested energy constraints are also indefinite quadratic constraints. Thus, [6], [7] used semi-definite relaxation (SDR) to relax such indefinite quadratic optimization problems to semi-definite programs (SDP) by dropping the matrix rank-one constraints on the outer products of beamforming vectors. The variable dimension of SDP is explosively large, and the beamforming vectors that are recovered based on the matrix solution of SDR perform poorly [8]. Moreover, SDR cannot be applied to throughput or EH maximization as the problems resultant by SDR are still highly nonconvex. Only recently there was an effective development to address these problems in [9] and [10].

Considering multi-input multi-output (MIMO) interference channels, information throughput and harvested energy, i.e., rate-energy (R-E) trade-off, was investigated in [11] and [12], assuming that any UE either acts as an ID receiver or an EH receiver. In case that UEs can operate both as an ID receiver and EH receiver (namely co-located cases), the R-E region of point-to-point MIMO channel was studied in [13]. Note that in MIMO networks, the information throughput function is involved with the determinant operation of a matrix and can no longer be expressed in the form of SINR. Consequently, the throughput constraints are always very challenging in precoding signals. [14], [15] used zero-forcing or interference-alignment to cancel all interferences, making the throughput functions concave in the signal covariance. The covariance optimization becomes convex but it is still computationally
called by PS problem and TS problem, respectively. They are both PS and TS are considered for the precoder designs and constraints in an FD EH-enabled multicell MU-MIMO network. Though TS-based system is practically easier to implement, the related formulated problem is quite complex because the throughput function in such case is coupled with the TS variable that defines the portion of time slot dedicated to EH and ID. This renders the aforementioned precoder design [14]–[16] for PS inapplicable. To the best of our knowledge, both the throughput maximization problem and the harvested energy maximization problem with TS are still very open.

All aforementioned works only assume that UEs only harvest energy arriving from BSs’ downlink (DL) transmission. In reality, UEs can also opportunistically harvest energy from other UEs’ signals during their uplink (UL) transmission. Furthermore, by allowing the BSs to simultaneously transmit and receive information, both the spectral efficiency and the amount of transferred energy will be improved. With the recent advances in antenna design and RF circuits in reducing self-interference (SI) [17]–[20], which is the interference from a BS’s DL transmission to its UL receiver, the full duplex (FD) technology is recently proposed as one of the key transceiving techniques for the fifth generation (5G) networks [20]–[24]. In this paper, we are interested in a network in which each FD multi-antenna BS simultaneously serves a group of UL UEs (ULUs) and a group of DL UEs (DLUs). In the same time, the BS also transfers energy to DLUs via TS or PS. FD transmission introduces even more interferences into the network by adding not only SI but also the interference from UL users (ULUs) toward downlink users (DLUs) and the interference from DL transmission of other BSs. Consequently, the UL and DL precoders are coupled in both DL and UL throughput functions, respectively, which makes the optimization problems for UL transmission and DL transmission inseparable.

In literature, [14], [25], [26] proposed covariance matrices design in (non-EH) FD MU-MIMO networks using D.C. iterations [27], which are still very computationally demanding as they require log-determinant function optimizations as mentioned above. Our previous work [16] has recently proposed a framework to directly find the optimal precoding matrices for the sum throughput maximization under throughput constraints in FD MU-MIMO multi-cell networks, which requires only a convex quadratic program of moderate size in each iteration and thus is very computationally efficient.

In this paper, we propose the design of efficient precoding matrices for the network sum throughput maximization under QoS in terms of MIMO throughput constraints and EH constraints in an FD EH-enabled multicell MU-MIMO network. Both PS and TS are considered for the precoder designs and called by PS problem and TS problem, respectively. They are quite challenging computationally due to nonconcave objective function and nonconvex constraints. However, we will see that the PS problem can be efficiently addressed by adapting the algorithm of [16]. On the other hand, the TS problem is much more challenging because the TS variable α is not only coupled with the DL throughput function but also coupled with the SI in the UL throughput function. It is nontrivial to extend [16] to solve the problem for the TS problem. Toward this end, we develop a new inner approximation of the original problem and solve the problem by a path-following algorithm. Finally, we also consider the FD EH maximization problem with throughput QoS constraints with TS. This problem also has a nonconvex objective function and nonconvex constraints and will be addressed by applying an approach similar to that of proposed for the TS problem.

The rest of this paper is organized as follows: Section II presents the system model the SCP algorithm of the PS problem. The main contribution of the paper is Section III and Section IV, which develop algorithms for the TS problem and FD EH maximization problem. Section V evaluates the performance of our devised solutions by numerical examples. Finally, Section VI concludes the paper.

Notation. All variables are boldfaced. I_n denotes the identity matrix of size n×n. The notation ( )^H stands for the Hermitian transpose. |A| denotes the determinant of a square matrix A and ⟨A⟩ denotes the trace of a matrix A. (A)^2 is Hermitian symmetric positive definite A AA^H. The inner product <X, Y> is defined as <X^HY^> and therefore the Frobenius squared norm of a matrix X is ||X||^2 = ⟨X^2⟩. The notation A ≥ B (A ∼ B, respectively) means that A − B is a positive semidefinite (define, respectively) matrix. E[.] denotes the expectation operator and ℜ{.} denotes the real part of a complex number.

The following concept of function approximation in [28] plays an important in our development.

Definition. A function ̇ is called a (global) minorant of a function ̼ at a point ̅ ̼ ̼ ̼ ̼ ̼ ̼ ̼ in the definition domain dom( ̇ ) of ̇ if ̇ (̅ ) = ̼ (̅ ) and ̼ ( ̼ ) ≥ ̼ ( ̼ ) ∀ ̼ ∈ dom( ̇ )

The following result [16] is used.

Theorem I: For function ̇ (V, Y) = ln [I_n + V^HV^V^{-1}V] in matrix variable V ∈ C^{n×m} and positive definite matrix variable Y ∈ C^{m×m}, the following quadratic function is its minorant at (V, Y)

̇ (V, Y) = ̇ + 2R{⟨A, V⟩} − ⟨B, V^HV + Y⟩,

where 0 ≥ A = ̇ (V, Y) − (V^HV^V^{-1}V), A = Y^(-1) and 0 ≥ B = Y^(-1) − (Y^(-1) V^HV + Y^(-1) V)^(-1).

II. EH-ENABLED FD MU-MIMO NETWORKS

We consider an MU-MIMO EH-enable network consisting of I cells. In cell i ∈ {1, ..., I}, a group of D DLUs in the downlink (DL) channel and a group of U ULUs in uplink (UL) channel are served by a BS i as illustrated in Fig. 1. Each BS operates in the FD mode and is equipped with N = N_1 + N_2 antennas, where N_1 antennas are used to transmit and the remaining N_2 antennas to receive signals. In cell i, DLU (i,jd) and ULU (i,ju) operate in the HD mode and each is equipped with N_r antennas. In the DL,
Fig. 1. Interference scenario in an FD multicell network, where SI denotes self-interference and ITI denotes the interference from the BS and ULUs of cell $i$.

Let $s_{i,j_0} \in \mathbb{C}^{d_1}$ be the symbol intended for DLU $(i,j_0)$ where $\mathbb{E} [s_{i,j_0}(s_{i,j_0})^H] = I_{d_1}$, $d_1$ is the number of concurrent data streams and $d_1 \leq \min \{N_1, N_r\}$. The vector of symbols $s_{i,j_0}$ is precoded and transmitted to DLU $(i,j_0)$ through the precoding matrix $V_{i,j_0} \in \mathbb{C}^{N_1 \times d_1}$. Analogously, in the UL, $s_{i,j_0} \in \mathbb{C}^{d_2}$ is the information symbols sent by ULU $(i,j_0)$ and is precoded by the precoding matrix $V_{i,j_0} \in \mathbb{C}^{N_2 \times d_2}$, where $\mathbb{E} [s_{i,j_0}(s_{i,j_0})^H] = I_{d_2}$, $d_2$ is the number of concurrent data streams and $d_2 \leq \min \{N_2, N_r\}$. For notational convenience, let us define

$$\mathcal{I} \triangleq \{1, 2, \ldots, I\}; \quad \mathcal{D} \triangleq \{1_D, 2_D, \ldots, D_D\};$$
$$\mathcal{U} \triangleq \{1_U, 2_U, \ldots, U_U\}; \quad S_1 \triangleq \mathcal{I} \times \mathcal{D}; \quad S_2 \triangleq \mathcal{I} \times \mathcal{U};$$
$$V_D = [V_{i,j_0}](i,j_0) \in S_1; \quad V_U = [V_{i,j_0}](i,j_0) \in S_2;$$
$$\mathbf{v} \triangleq \{V_D, V_U\};$$

In the DL channel, the received signal at DLU $(i,j_0)$ is expressed as:

$$y_{i,j_0} \triangleq H_{i,j_0} V_{i,j_0} s_{i,j_0} + \sum_{(m,\ell_0) \in \mathcal{S}_1 \setminus (i,j_0)} H_{m,i,j_0} V_{m,\ell_0} s_{m,\ell_0} + \sum_{\ell_0 \in \mathcal{U}} H_{i,j_0,\ell_0} V_{i,\ell_0} s_{i,\ell_0} + n_{i,j_0}, \quad (1)$$

where $H_{m,i,j_0} \in \mathbb{C}^{N_2 \times N_1}$ and $H_{i,j_0,\ell_0} \in \mathbb{C}^{N_2 \times N_r}$ are the channel matrices from BS $m$ to DLU $(i,j_0)$ and from ULU $(i,\ell_0)$ to DLU $(i,j_0)$, respectively. Also, $n_{i,j_0}$ is the additive white circularly symmetric complex Gaussian noise with variance $\sigma_n^2$. In this work, the UL intercell interference is neglected since it is very small compared to the DL intercell interference due to the much smaller transmit power of ULUs. Nevertheless, it can be incorporated easily in our formulation.

Assuming that DLUs are equipped by both devices for ID and EH, the power splitting technique is applied at each DLU to simultaneously conduct information decoding and energy harvesting. The power splitter divides the received signal $y_{i,j_0}$ into two parts in the proportion of $\alpha_{i,j_0} : (1 - \alpha_{i,j_0})$ where $\alpha_{i,j_0} \in (0,1)$ is termed as the PS ratio for DLU $(i,j_0)$. In particular, the signal split to the ID receiver of DLU $(i,j_0)$ is given by

$$\sqrt{\alpha_{i,j_0}} y_{i,j_0} + z_{i,j_0}^c, \quad (2)$$

where each $r$-th element of $z_{i,j_0}^c$ (i.e., $|z_{i,j_0}^c|^2 = \sigma_n^2$, $r = 1, \ldots, N_r$) is additional noise introduced by the ID receiver circuitry. An EH receiver processes the second part of the split signal $\sqrt{1 - \alpha_{i,j_0}} y_{i,j_0}$ for the harvested energy

$$\sqrt{\zeta_{i,j_0}(1 - \alpha_{i,j_0})} y_{i,j_0},$$

where $\zeta_{i,j_0} \in (0, 0.6)$ is the efficiency of energy conversion.

It follows from the receive equation (1) and the split equation (2) that the downlink information throughput at DLU $(i,j_D)$ is

$$f_{i,j_D}(V_D, V_U, \alpha_{i,j_D}) \triangleq \ln \left[ |I_N, \mathcal{L}_{i,j_D}(V_{i,j_D})|^2 \Psi_{i,j_D}^{-1}(V_D, V_U, \alpha_{i,j_D}) \right], \quad (3)$$

where $\mathcal{L}_{i,j_D}(V_{i,j_D}) \triangleq H_{i,j_D} V_{i,j_D}$ and

$$\Psi_{i,j_D}(V_D, V_U, \alpha_{i,j_D}) \triangleq \Psi_{i,j_D}(V_D, V_U) + (\sigma_n^2/\alpha_{i,j_D}) I_N, \quad (4)$$

with the downlink interference covariance mapping

$$\bar{\Psi}_{i,j_D}(V_D, V_U) \triangleq \sum_{(m,\ell_0) \in \mathcal{S}_1 \setminus (i,j_0)} (H_{m,i,j_D} V_{m,\ell_0})^2 + \sum_{\ell_0 \in \mathcal{U}} (H_{i,j_0,\ell_0} V_{i,\ell_0})^2 + \sigma_D I_N, \quad (5)$$

The harvested energy at UE $(i,j_0)$ is

$$E_{i,j_0}(V_D, V_U, \alpha_{i,j_D}) = \zeta_{i,j_0}(1 - \alpha_{i,j_D}) (\Phi_{i,j_D}(V_D, V_U), (6))$$

with the downlink signal covariance mapping

$$\Phi_{i,j_D}(V_D, V_U) \triangleq \sum_{(m,\ell_0) \in \mathcal{S}_1} (H_{m,i,j_D} V_{m,\ell_0})^2$$

$$+ \sum_{\ell_0 \in \mathcal{U}} (H_{i,j_0,\ell_0} V_{i,\ell_0})^2 + \sigma_D^2 I_N. \quad (7)$$

In the UL channel, the received signal at BS $i$ is expressed as

$$y_i \triangleq \sum_{\ell \in \mathcal{U}} H_{i,\ell_0} V_{i,\ell_0} s_{i,\ell_0}$$

$$+ \sum_{m \in \mathcal{I}_1 \setminus \{i\}} \sum_{\ell \in \mathcal{U}} H_{m,i,\ell_0} V_{m,\ell_0} s_{m,\ell_0}$$

$$+ \sum_{m \in \mathcal{I}_1 \setminus \{i\}} \sum_{j \in \mathcal{D}} H_{m,j} V_{m,j} s_{m,j} + n_i, \quad (8)$$

where $H_{m,\ell_0}$ and $H_{m,j}$ are the channel matrices from ULU $(m,\ell_0)$ to BS $i$ and from BS
where $\sigma^2_{SI}$ is the residual SI (after self-interference cancellation) at BS $i$ and depends on the transmit power of BS $i$. Specifically, $\sigma^2_{SI}$ is modelled as the additive white circularly symmetric complex Gaussian noise with variance $\sigma^2_{SI}$ [29], where the SI level $\sigma^2_{SI}$ is the ratio of the average SI powers after and before the SI cancellation process.

Following [14], [16], [26], the optimal minimum mean square error - Successive interference cancellation (MMSE-SIC) decoder is applied at BSs. Therefore, the achievable uplink throughput at BS $i$ is given as [30]

$$f_i(V_D, V_U) \triangleq \ln \left| I_{N_2} + (\mathcal{L}_i(V_{U_i}))^2 \Psi_i^{-1}(V_D, V_U) \right|, \quad (9)$$

where $V_{U_i} \triangleq [V_{i,1}, \ldots, V_{i,\ell}]$ and $\mathcal{L}_i(V_{U_i}) \triangleq \left[H_{i,1,1}, \ldots, V_{i,\ell}, H_{i,1,2}, \ldots, H_{i,\ell,1}, V_{i,\ell} \cdots U_i \right]$, which means

that $(\mathcal{L}_i(V_{U_i}))^2 = \sum_{\ell=1}^\infty (H_{i,1,\ell}V_{i,\ell}I_{N_2})^2$; and

$$\Psi_i(V_D, V_U) \triangleq \Phi_i^U(V_U) + \Phi_i^{SI}(V_D) \quad (10)$$

with uplink interference covariance mapping

$$\Phi_i^U(V_U) \triangleq \sum_{m \in \mathcal{I} \setminus \{i\}} \sum_{\ell \in \mathcal{D}} (H_{m,1,\ell}V_{m,\ell})^2 + \sum_{m \in \mathcal{I} \setminus \{i\}} \left( \sum_{\ell \in \mathcal{D}} (V_{m,\ell})^2 \right) (H_{m,1}^H + \sigma^2_{SI}I_{N_2}) \quad (11)$$

and SI covariance mapping

$$\Phi_i^{SI}(V_D) \triangleq \sigma^2_{SI} \sum_{\ell \in \mathcal{D}} \|V_{i,\ell}\|^2I_{N_2}. \quad (12)$$

We consider the design problem

$$\max_{V_D, V_U, \alpha} P_{i}(V_D, V_U, \alpha) \triangleq \sum_{i \in \mathcal{I}} f_i(V_D, V_U) + \sum_{(i,j) \in S_1} f_{i,j_0}(V_D, V_U, \alpha_{i,j_0}) \quad \text{s.t.} \quad (13a)$$

$$0 < \alpha_{i,j_0} < 1, (i, j_0) \in S_1, \quad (13b)$$

$$\sum_{(i,j) \in S_1} \|V_{i,j}\|^2 + \sum_{(i,j) \in S_2} \|V_{i,j}\|^2 \leq P, \quad (13c)$$

$$\sum_{j_0 \in \mathcal{D}} \|V_{i,j_0}\|^2 \leq P_{i,j_0}, (i,j_0) \in S_1, \quad (13d)$$

$$(\Phi_{i,j_0}(V_D, V_U)) = \sum_{i,j_0} (f_{i,j_0}(V_D, V_U), 1 - \alpha_{i,j_0}), \quad (13e)$$

$$f_{i,j_0}(V_D, V_U) \geq r_{i,j_0}^\text{min}, (i,j_0) \in S_1, \quad (13f)$$

$$f_{i,j_0}(V_D, V_U) \geq r_{i,j_0}^\text{min}, \forall (i,j_0) \in S_1. \quad (13g)$$

In the formulation (13), all channel matrices in the downlink equation (1) and uplink (8) are assumed to be known by using the channel reciprocity, feedback and learning mechanisms (see e.g. [31]). The convex constraints (13d) and (13e) specify the maximum transmit power available at the BSs and the ULUs whereas (13c) limits the total transmit power of the whole network. The nonconvex constraints (13f), (13g) and (13h) represent QoS guarantee, where $r_{i,j_0}^\text{min}$ and $r_{i,j_0}^\text{min}$ are the minimum harvested energy required by DLU $(i,j_0)$, the minimum data throughput required by BS $i$ and the minimum data throughput required by DLU $(i,j_0)$. In comparison to [16] for FD non-EH-enable networks, the UL throughput function $f_i(V_D, V_U)$ in (9) is the same, where the DL throughput function $f_{i,j_0}(V_D, V_U, \alpha_{i,j_0})$ is now additionally dependent on the SP variable $\alpha_{i,j_0}$, decoupled in (5) and thus does not add more difficulty as we will show now. We also show that the nonconvex EH constraints (13f) can easily be innerly approximated.

Under the definitions,

$$\mathcal{M}_{i,j_0}(V_D, V_U, \alpha_{i,j_0}) \triangleq (\mathcal{L}_{i,j_0}(V_{i,j_0}))^2 + \sum_{\ell \in \mathcal{D}} (\mathcal{L}_{i,j_0}(V_{i,j_0}))^2 \Psi\left(V_D, V_U, \alpha_{i,j_0}\right) \quad (14)$$

$$\mathcal{M}_{i,j_0}(V_D, V_U) \triangleq (\mathcal{L}_{i,j_0}(V_{i,j_0}))^2 + \sum_{\ell \in \mathcal{D}} (\mathcal{L}_{i,j_0}(V_{i,j_0}))^2 \Psi\left(V_D, V_U, \alpha_{i,j_0}\right) \quad (15)$$

by applying Theorem 1 as in [16], we obtain the following concave quadratic minors of throughput functions $f_{i,j_0}(V_D, V_U, \alpha_{i,j_0})$ and $f_{i,j_0}(V_D^\text{min}, V_U^\text{min})$ at $(V_D^\text{min}, V_U^\text{min})$:

$$\theta_{i,j_0}(V_D, V_U, \alpha_{i,j_0}) \triangleq \sum_{j_0 \in \mathcal{D}} (\mathcal{L}_{i,j_0}(V_{i,j_0}))^2 = \sum_{j_0 \in \mathcal{D}} \left( \sum_{\ell \in \mathcal{D}} (V_{i,j_0})^2 \right) (H_{m,1}^H + \sigma^2_{SI}I_{N_2}) \quad (16)$$

and

$$\theta_{i,j_0}(V_D, V_U, \alpha_{i,j_0}) \triangleq \sum_{j_0 \in \mathcal{D}} (\mathcal{L}_{i,j_0}(V_{i,j_0}))^2 = \sum_{j_0 \in \mathcal{D}} \left( \sum_{\ell \in \mathcal{D}} (V_{i,j_0})^2 \right) (H_{m,1}^H + \sigma^2_{SI}I_{N_2}) \quad (17)$$

where

$$0 > a_{i,j_0}^\text{c} \triangleq \sum_{j_0 \in \mathcal{D}} (\mathcal{L}_{i,j_0}(V_{i,j_0}))^2 - \sum_{j_0 \in \mathcal{D}} \left( \sum_{\ell \in \mathcal{D}} (V_{i,j_0})^2 \right) \Psi\left(V_D, V_U, \alpha_{i,j_0}\right) \quad (18)$$

and

$$0 > a_{i,j_0}^\text{c} \triangleq \sum_{j_0 \in \mathcal{D}} (\mathcal{L}_{i,j_0}(V_{i,j_0}))^2 - \sum_{j_0 \in \mathcal{D}} \left( \sum_{\ell \in \mathcal{D}} (V_{i,j_0})^2 \right) \Psi\left(V_D, V_U, \alpha_{i,j_0}\right) \quad (19)$$

To handle the nonconvex EH constraints (13f), we define an affine function $\phi_{i,j_0}(V_D, V_U)$ as the first-order approximation
Algorithm 1 Path-following algorithm for PS sum throughput maximization (13)

Initialization: Set $\kappa := 0$, and choose a feasible point
$(V_D^{(0)}, V_U^{(0)}, \alpha^{(0)})$ that satisfies (13b)-(13h).

$k$-th iteration: Solve (23) for an optimal solution
$(V_D^*, V_U^*, \alpha^*)$ and set $\kappa := \kappa + 1$, $(V_D^{(\kappa)}, V_U^{(\kappa)}, \alpha^{(\kappa)}) :=
(V_D^*, V_U^*, \alpha^*)$ and calculate $P_1(V_D^{(\kappa)}, V_U^{(\kappa)}, \alpha^{(\kappa)})$. Stop if
\[
\frac{P_1(V_D^{(\kappa)}, V_U^{(\kappa)}, \alpha^{(\kappa)}) - P_1(V_D^{(\kappa-1)}, V_U^{(\kappa-1)}, \alpha^{(\kappa-1)})}{P_1(V_D^{(\kappa-1)}, V_U^{(\kappa-1)}, \alpha^{(\kappa-1)})} \leq \epsilon.
\]

of the convex function $\langle \Phi_{i,j0}(V_D, V_U) \rangle$ at $(V_D^{(\kappa)}, V_U^{(\kappa)})$:
\[
\phi_{i,j0}^{(\kappa)}(V_D, V_U) \triangleq -\langle \Phi_{i,j0}^{(\kappa)}(V_D, V_U) \rangle + 2\Re\{ \sum_{m,\ell \in \mathcal{S}} \{H_{m,i,j0} V_D^{(\kappa)} V_{U,m,l0} H_{m,i,j0}^H \} \}
+ 2\Re\{ \sum_{\ell \in \mathcal{H}} \{H_{i,j0,\ell} U_D^{(\kappa)} H_{i,j0,\ell}^H \} \} + 2\sigma_D^2 N_r,
\]
which is an minorant of $\langle \Phi_{i,j0}(V_D, V_U) \rangle$ at $(V_D^{(\kappa)}, V_U^{(\kappa)})$ [28].

We now address the nonconvex problem (13) by successively solving its following inner approximation:
\[
\max_{V_D, V_U, \alpha} P_1^{(\kappa)}(V_D, V_U, \alpha) \triangleq \sum_{i \in \mathcal{I}} \Theta_i^{(\kappa)}(V_D, V_U)
+ \sum_{(i,j,0) \in \mathcal{S}_1} \Theta_{i,j,0}^{(\kappa)}(V_D, V_U, \alpha_{i,j,0})
\text{s.t. } (13b)-(13e),
\]
\[
\phi_{i,j0}^{(\kappa)}(V_D, V_U) \geq \frac{\min_{i,j,0} e_{i,j,0}}{\ell_{i,j,0} (1-\alpha_{i,j,0})},
\forall (i,j,0) \in \mathcal{S}_1,
\]
\[
\Theta_i^{(\kappa)}(V_D, V_U, \alpha_{i,j,0}) \geq \hat{r}_i^{\text{min}}, \forall i \in \mathcal{I},
\]
(23a)
(23b)
(23c)
(23d)
(23e)

Initializing from $(V_D^{(\kappa)}, V_U^{(\kappa)}, \alpha^{(\kappa)})$ being feasible point to (13), the optimal solution $(V_D^{(\kappa+1)}, V_U^{(\kappa+1)}, \alpha^{(\kappa+1)})$ of convex program (23) is feasible to the nonconvex program (13) and it is better than $(V_D^{(\kappa)}, V_U^{(\kappa)}, \alpha^{(\kappa)})$:
\[
P_1(V_D^{(\kappa+1)}, V_U^{(\kappa+1)}, \alpha^{(\kappa+1)}) \geq P_1^{(\kappa)}(V_D^{(\kappa)}, V_U^{(\kappa)}, \alpha^{(\kappa)}).
\]
(24)

where the inequality (24) and the equality (26) follow from the fact that $P_1^{(\kappa)}$ is a minorant of $P_1$ while the inequality (25) follows from the fact that $(V_D^{(\kappa+1)}, V_U^{(\kappa+1)}, \alpha^{(\kappa+1)})$ and $(V_D^{(\kappa)}, V_U^{(\kappa)}, \alpha^{(\kappa)})$ are the optimal solution and feasible point of (23), respectively. This generates a sequence $\{V_D^{(\kappa)}, V_U^{(\kappa)}, \alpha^{(\kappa)}\}$ of feasible and improved points which converge to a local optimum of (13) after finitely many iterations [16].

The proposed path-following procedure that solves problem (13) is summarized in Algorithm 1. To find a feasible initial point $(V_D^{(0)}, V_U^{(0)}, \alpha^{(0)})$ meeting the nonconvex constraints (13f)-(13h) we consider the following problem:
\[
\max_{V_D, V_U, \alpha} P_1(f)(V_D, V_U, \alpha) \triangleq \min_{(i,j,0) \in \mathcal{S}_1} \{ \phi_{i,j0}^{(\kappa)}(V_D, V_U) - \frac{r_{i,j0}^\min}{\ell_{i,j0}(1-\alpha_{i,j,0})} \}
\geq \frac{e_{i,j,0}^\min}{\ell_{i,j,0}(1-\alpha_{i,j,0})},
\forall (i,j,0) \in \mathcal{S}_1.
\]

which terminates upon reaching
\[
f_{i,j0}(V_D^{(\kappa)}, V_U^{(\kappa)}, \alpha^{(\kappa)}) \geq r_{i,j0}^\min, f_i(V_D^{(\kappa)}, V_U^{(\kappa)}) \geq r_i^\min,
\]
\[
\langle \phi_{i,j0}^{(\kappa)}(V_D, V_U, \alpha) \rangle \geq \frac{e_{i,j,0}^\min}{\ell_{i,j,0}(1-\alpha_{i,j,0})}, \forall (i, j, 0) \in \mathcal{S}_1
\]
(27)

(28)

In parallel, we consider the following transmission strategy to configure FD BSs to operate in the HD mode. Here, all antennas $N = N_1 + N_2$ at each BS are used to serve all the DLUs in the downlink and all the ULUs in the uplink using half time slots, where DLUs are allowed to harvest energy from ULUs. The problem can be formulated as
\[
\max_{V_D, V_U, \alpha} \frac{1}{2} \sum_{(i,j,0) \in \mathcal{S}_1} f_{i,j0}(V_D, 0_U, \alpha_{i,j,0})
+ \sum_{i \in \mathcal{I}} f_i(0_D, V_U)
\text{s.t. } (13b)-(13e),\]
\[
\frac{1}{2}(E_{i,j,0}(V_D, 0_U, \alpha_{i,j,0}) + E_{i,j,0}(0_D, V_U, 0)) \geq e_{i,j,0}^{\text{min}}, \forall (i,j,0) \in \mathcal{S}_1,
\]
\[
\frac{1}{2} f_i(0_D, V_U) \geq r_i^{\text{min}}, \forall i \in \mathcal{I},
\]
\[
\frac{1}{2} f_{i,j0}(V_D, 0_U, \alpha_{i,j,0}) \geq r_{i,j0}^{\text{min}}, \forall (i,j,0) \in \mathcal{S}_1,
\]
(29a)
(29b)
(29c)
(29d)

where $0_D$ and $0_U$ are zero quantity of the same dimension with $V_D$ and $V_U$. In (29), DLU $(i,j,0)$ uses $(1-\alpha_{i,j,0})$ of the received signal during DL transmission and the whole received signal during UL transmission for EH as formulated in (29b). The main difference between (13) and (29) is in (29b) where the harvested energy from UL transmission at DLU $(i,j,0)$ does not multiply with $\alpha_{i,j,0}$. The constraint (29b) can be recast as
\[
\langle \phi_{i,j0}^{(\kappa)}(V_D, 0_U) \rangle \geq \frac{r_{i,j0}^{\text{min}}}{(1-\alpha_{i,j,0})},
\]
Define the following convex function:
\[
\Lambda_{i,j,o}(V_U, \alpha_{i,j,o}) \triangleq \frac{\langle \Phi_{i,j,o}(0_D, V_U) \rangle}{(1 - \alpha_{i,j,o})}
= \frac{\langle \sum_{t \in \mathcal{L}} (H_{i,j,o,0} V_{i,t})^2 + \sigma_D^2 I_{N_r} \rangle}{1 - \alpha_{i,j,o}},
\]
with its first-order approximation
\[
\Lambda_{i,j,o}^{(\kappa)}(V_U, 1 - \alpha_{i,j,o}) \triangleq \frac{2 \Re\{\langle \sum_{t \in \mathcal{L}} (H_{i,j,o,0} V_{i,t})^2 + \sigma_D^2 I_{N_r} \rangle\}}{1 - \alpha_{i,j,o}} - \frac{\langle \sum_{t \in \mathcal{L}} (H_{i,j,o,0} V_{i,t}^{(\kappa)})^2 + \sigma_D^2 I_{N_r} \rangle}{(1 - \alpha_{i,j,o})^2},
\]
which is its minorant at \((V_D^{(\kappa)}, V_U^{(\kappa)}, \alpha^{(\kappa)})\).

Algorithm 1 can be used with the following convex program solved for \(\kappa\)-iteration:
\[
\begin{align*}
\max_{V_U, V_D, \alpha} & \quad \frac{1}{2} \sum_{(i,j,o) \in S_t} \Theta_{\kappa,j,o}(V_D, 0_U, \alpha_{i,j,o}) \\
\text{s.t.} & \quad (13b), (13c), (13d), (13e), \\
& \quad \phi_{i,j,o}^{(\kappa)}(V_D, 0_U) + \Lambda_{i,j,o}^{(\kappa)}(V_U, 1 - \alpha_{i,j,o}) \geq 2 \min_{i,j,o} \gamma(i, j, o) \in S_1, \\
& \quad \frac{1}{2} \Theta_{i,j,o}^{(\kappa)}(0_U, V_D) \geq r_{i,j,o}^{\text{min}}, \forall i \in \mathcal{I}, \\
& \quad \frac{1}{2} \Theta_{i,j,o}^{(\kappa)}(V_D, 0_U, \alpha_{i,j,o}) \geq r_{i,j,o}^{\text{min}}, \forall (i, j, o) \in S_1,
\end{align*}
\]  

where \(\phi_{i,j,o}^{(\kappa)}(V_D, 0_U)\) and \(\Theta_{i,j,o}^{(\kappa)}(V_D, 0_U, \alpha_{i,j,o})\) are defined by (22) and (18) with both \(V_D\) and \(V_U^{(\kappa)}\) replaced by \(0_U\), while \(\Theta_{i,j,o}^{(\kappa)}(0_U, V_D)\) is defined by (19) with both \(V_D\) and \(V_U^{(\kappa)}\) replaced by \(0_U\).

Problems (23), (28) and (32) involve \(n = 2(N_d d_d I_D + N_r d_r I_U) + I_D\) scalar real decision variables and \(m = 5 I_D + I_U + I_D + I_U + 2 I_U + 1\) quadratic constraints so their computational complexity is \(O(n^2 m^{2.5} + m^{3.5})\).

III. EH-ENABLED FD MU-MIMO BY TS

A much easier implementation is time splitting \(0 < \alpha < 1\) in downlink transmission where \((1 - \alpha)\) time is used for DL energy transfer and \(\alpha\) time is used for DL information transmission. In this section, we define \(V_D^{I} \triangleq [V_{i,j,o}^{I}]_{(i,j,o) \in S_1}, V_D^{E} \triangleq [V_{i,j,o}^{E}]_{(i,j,o) \in S_1}\) and redefine the notation \(V_D \triangleq [V_D^{I}, V_D^{E}]\) where \(V_D^{I}\) and \(V_D^{E}\) are the information precoding matrix for ID and energy precoding matrix for EH, respectively. The received signal at DLU \((i, j, o)\) for EH is
\[
y_{i,j,o}^{E} \triangleq \sum_{(m, t) \in S_1} H_{i,j,o, m,t} V_{m,t}^{E} s_{m,t,0}^{E} + \sum_{(i, b) \in \mathcal{L}} H_{i,j,o, i,b} V_{i,b} s_{i,b,0} + n_{i,j,o},
\]
where \(s_{m,t,0}^{E}\) is the energy signal sent for \((1 - \alpha)\) time. With the definition (6), the harvested energy is
\[
E_{i,j,o}(V_D^{E}, V_U, \alpha) = \zeta_{i,j,o}(1 - \alpha) \langle \Phi_{i,j,o}(V_D^{E}, V_U) \rangle,
\]
where the downlink signal covariance mapping \(\Phi_{i,j,o}(. , .)\) is defined from (7).

Similarly to (1), the signal received at DLU \((i, j, o)\) during the information transmission in time fraction \(\alpha\) is
\[
y_{i,j,o}^{I} \triangleq H_{i,i,j,o} V_{i,j,o} s_{i,j,o}^{I}
\]
\[
\text{desired signal} + \sum_{(m, t) \in S_1} H_{m,i,j,o} V_{m,t} s_{m,t,0}^{I} + n_{i,j,o},
\]

where \(s_{m,t,0}^{I}\) is the information signal intended for DLU \((m, t)\). The ID throughput at DLU \((i, j, o)\) is then given as \(\alpha f_{i,j,o}(V)\), where
\[
f_{i,j,o}(V_D^{I}, V_U) = \ln \left| I_{N_r} + (L_{i,j,o}(V_{i,j,o}^{I}))^2 \Psi_{i,j,o}^{-1}(V_D^{I}, V_U) \right|,
\]
with the downlink interference covariance mapping \(\Psi_{i,j,o}^{(\cdot)}\) defined from (5).

The uplink throughput at the BS is
\[
f_i(V_D, V_U, \alpha) \triangleq \ln \left| I_{N_d} + (L_i(V_U)) \Psi_i^{-1}(V_D, V_U, \alpha) \right|,
\]
where \(L_i(V_U)\) is already defined from (9) but
\[
\Psi_{i}(V_D, V_U, \alpha) \triangleq \Psi_{i}(V_U) + \Psi_{i\text{SI}}^{TS}(V_D, \alpha)
\]
with the uplink interference covariance mapping \(\Psi_{i}^{U}(\cdot)\) defined by (11) and the time-splitting SI covariance mapping
\[
\Psi_{i}^{TS}(V_D, \alpha) \triangleq \Psi_{i}^{S}\sum_{j \in D} ((1 - \alpha) ||V_{i,j}||^2 + \alpha ||V_{i,j}||^2) I_{N_d}.
\]
Problem (39) is much more difficult computationally than (13). Firstly, the DL throughput is now the multiplication of data throughput and the portion of time $1/\rho$. Secondly, the SI in UL throughput is also coupled with $1/\rho$. Finally, the power constraints (41b), (41c) are also coupled with $1/\rho$. Therefore, the objective function (41a) and constraints (41b)-(41f) are all nonconvex and cannot be addressed as in (13). In the following, we will develop the new minorants of the DL throughput function and UL throughput function.

Firstly, we address a lower approximation of each $f_{i,j_0}(V_{D_i}^*, V_u^*)/\rho$ in (41a) and (41f). Recalling the definition (35) of $f_{i,j_0}(V_{D_i}^*, V_u^*)$ we introduce

$$\mathcal{M}_{i,j_0}(V_{D_i}^*, V_u^*) \triangleq \left( \mathcal{L}_{i,j_0}(V_{i,j_0}^*) \right)^2 + \bar{\Psi}_i(V_u) - \langle B^{(i_j_0)}, M_{i,j_0}(V_{D_i}^*, V_u^*) \rangle \rho \right),$$

where similarly to (20)

$$0 > a^{(i_j_0)}_{i,j_0} = f_{i,j_0}(V_{D_i}^*, V_u^*) / \rho$$

Under (45), we have

$$\mathcal{M}_{i,j_0}(V_{D_i}^*, V_u^*) \geq 0, \ (i,j_0) \in S_1 \tag{45}$$

Therefore, the following concave function

$$g_{i,j_0}^{(i_j_0)}(V_{D_i}^*, V_u^*) \triangleq \frac{a^{(i_j_0)}_{i,j_0}}{\rho} + 4d^{(i_j_0)}_{i,j_0} \sqrt{R \left\{ (A_{i,j_0}^{(i_j_0)}, L_{i,j_0}(V_{i,j_0}^*)) \right\}} - 2c^{(i_j_0)}_{i,j_0} \rho$$

is a minorant of $f_{i,j_0}(V_{D_i}^*, V_u^*)/\rho$ at $(V_{D_i}^*, V_u^*)/\rho$.

Next, we address a lower approximation of $f_{i,j_0}(V_{D_i}^*, V_u^*)$ in (41a). (41f). Recalling the definition (36) of $f_{i,j_0}(V_{D_i}^*, V_u^*)$ we introduce

$$\mathcal{M}_{i,j_0}(V_{D_i}^*, V_u^*) \triangleq \left( \mathcal{L}_{i,j_0}(V_{i,j_0}^*) \right)^2 + \bar{\Psi}_i(V_u) - \langle B^{(i_j_0)}, M_{i,j_0}(V_{D_i}^*, V_u^*) \rangle \rho \right),$$

Constraints (39c), (39d) and (39e) limits the transmit power of each ULU, the whole network and each BS, respectively. Constraints (39h) ensures that each DLUs harvest more than a threshold whereas constraints (39f) and (39g) guarantee the throughput QoS at BSs and DLUs, respectively. The key difficulty in problem (39) is to handle the time splitting factor $\alpha$ that is coupled with the objective functions and other variables. Using the variable change $\rho = 1/\alpha$, which satisfies the convex constraint

$$\rho > 1, \tag{40}$$

problem (39) is equivalent to

$$\max_{V_0, V_u, \rho > 0} \mathcal{M}_{i,j_0}(V_{D_i}^*, V_u^*) \triangleq \sum_{(i,j_0) \in S_1} f_{i,j_0}(V_{D_i}^*, V_u^*) / \rho + \sum_{i \in I} f_i(V_{D_i}, V_u, 1/\rho)$$

s.t. (40), (39c),

$$\sum_{(i,j_0) \in S_1} (||V_{i,j_0}^E||^2 + ||V_{i,j_0}^L||^2) \leq P + \sum_{(i,j_0) \in S_1} ||V_{i,j_0}^E||^2 / \rho$$

$$\sum_{j_0 \in D} \left( ||V_{i,j_0}^E||^2 + ||V_{i,j_0}^L||^2 / \rho \right) \leq P + \sum_{(i,j_0) \in S_1} ||V_{i,j_0}^E||^2 / \rho, \forall i \in I, \tag{41c}$$

$$E_{i,j_0}(V_{D_i}, V_u, 1/\rho) \geq d^{(i,j_0)}_{i,j_0}, \forall (i,j_0) \in S_1, \tag{41d}$$

$$f_i(V_{D_i}, V_u, 1/\rho) \geq r^{(i,j_0)}_{i,j_0}, \forall i \in I, \tag{41e}$$

$$f_{i,j_0}(V_{D_i}, V_u) / \rho \geq r^{(i,j_0)}_{i,j_0}, \forall (i,j_0) \in S_1. \tag{41f}$$
for $\tilde{\Psi}_i^{TSI}(V_D, 1/\rho)$ defined from (38) as
\[
\tilde{\Psi}_i^{TSI}(V_D, 1/\rho) = \sigma_{SI}^2 \sum_{j \in D} \left( \|V_{i,j0}^E\|^2 + \frac{1}{\rho} \|V_{i,j0}\|^2 - \frac{1}{\rho} \|V_{i,j0}^E\|^2 \right) I_{N_2},
\]
(50)
to have its following minorant at $(V_D^{(k)}, V_U^{(k)}, \rho^{(k)})$:
\[
\Theta_i^{(k)}(V_D, V_U, \rho) \triangleq \alpha_i^{(k)} + 2 \Re \left\{ \langle A_i^{(k)}, L_i(V_U) \rangle \right\} - \langle B_i^{(k)}, M_i(V_D, V_U, \rho) \rangle,
\]
(51)
where similarly to (21)
\[
0 > \beta_i^{(k)}(V_D, V_U, \rho) = \langle \Psi_i^{-1}(V_D^{(k)}, V_U^{(k)}), L_i(V_U^{(k)}) \rangle.
\]
(52)
Function $\Theta_i^{(k)}(V_D, V_U, \rho)$ is not concave due to the term $\tilde{\Psi}_i^{TSI}(V_D, 1/\rho)$ defined by (50). However, the following matrix inequality holds true:
\[
\frac{1}{\rho} \|V_{i,j0}^E\|^2 I_{N_2} \geq \left( \frac{2}{\rho} \right) \Re \{ \langle V_{i,j0}^{E,(k)}, V_{i,j0}^E \rangle \} - \frac{\|V_{i,j0}^E\|^2}{\rho^2} I_{N_2},
\]
(53)
which yields the matrix inequality
\[
\frac{M_i}{\lambda_i^{(k)}}(V_D, V_U, \rho) \geq \lambda_i^{(k)}(V_D, V_U, \rho) \triangleq \langle L_i(V_U), \rho \rangle + \left( \langle L_i^U(V_U), \rho \rangle + \sigma_{SI}^2 \right) \left( \|V_{i,j0}^E\|^2 + \frac{1}{\rho} \|V_{i,j0}\|^2 \right)
- \frac{2}{\rho} \Re \{ \langle V_{i,j0}^{E,(k)}, V_{i,j0}^E \rangle \} + \frac{\|V_{i,j0}^E\|^2}{\rho^2} I_{N_2}.
\]
As $B_i^{(k)} \geq 0$ by (52), we then have
\[
\langle B_i^{(k)}, M_i(V_D, V_U, \rho) \rangle \geq \langle B_i^{(k)}, \lambda_i^{(k)}(V_D, V_U, \rho) \rangle
\]
so a concave minorant of both $f_i(V_D, V_U, 1/\rho)$ and $\Theta_i^{(k)}(V_D, V_U, \rho)$ is
\[
\tilde{\Theta}_i^{(k)}(V_D, V_U, \rho) \triangleq \alpha_i^{(k)} + 2 \Re \left\{ \langle A_i^{(k)}, L_i(V_U) \rangle \right\} - \langle B_i^{(k)}, \lambda_i^{(k)}(V_D, V_U, \rho) \rangle,
\]
(54)
Concerned with $\|V_{i,j0}^E\|^2 / \rho$ in the right hand side (RHS) of (41b) and (41c), it follows from (53) that
\[
\|V_{i,j0}^E\|^2 / \rho \geq \gamma_i^{(k)}(V_D^{(k)}, V_U^{(k)}, \rho) \triangleq 2 \Re \{ \langle V_{i,j0}^{E,(k)}, V_{i,j0}^E \rangle \} / \rho^2 - \rho \|V_{i,j0}^E\|^2 / \rho^2.
\]
(55)
We also have $\phi_i^{(k)}(V_D^E, V_U)$ defined in (22) as a minorant of $\langle \Psi_i, j0(V_D^E, V_U) \rangle$. We now address the nonconvex problem (41) by successively solving its following innerly approximated convex program at $\kappa$-iteration:
\[
\max_{\mathbf{v}_D, \mathbf{v}_U, \rho > 0} P_2^{(k)}(V_D, V_U, \rho)
\]
s.t. (40), (39c),
(55a)
\[
\sum_{(i,j0) \in S_1} \left( \|V_{i,j0}^E\|^2 + \frac{1}{\rho} \|V_{i,j0}\|^2 \right) + \sum_{(i,j0) \in S_2} \|V_{i,j0}\|^2 \leq P + \sum_{(i,j0) \in S_1} \gamma_i^{(k)}(V_{i,j0}, \rho),
\]
(55b)
\[
\sum_{(i,j0) \in D} \left( \|V_{i,j0}^E\|^2 + \frac{1}{\rho} \|V_{i,j0}\|^2 \right) \leq P_i + \sum_{(i,j0) \in D} \gamma_i^{(k)}(V_{i,j0}, \rho), \forall i \in I,
\]
(55c)
\[
\phi_i^{(k)}(V_D^E, V_U) \geq \epsilon_i^{\max}(1 + \frac{1}{\rho - 1}) / \zeta_{i,j0}, \forall (i,j0) \in S_1,
\]
(55d)
\[
\tilde{\Theta}_i^{(k)}(V_D, V_U, \rho) \triangleq \sum_{i \in I} \tilde{\Theta}_i^{(k)}(V_D, V_U, \rho) + \sum_{(i,j0) \in S_1} g_i^{(k)}(V_D^E, V_U),
\]
(55e)
A path-following algorithm similar to Algorithm 1 can be applied to solve (41) as summarized in Algorithm 2. Thanks to the following relation, which is similar to (26):
\[
P_2(V_D^{(k+1)}, V_U^{(k+1)}, \rho^{(k+1)}) \geq P_2(V_D^{(k)}, V_U^{(k)}, \rho^{(k)}),
\]
(56)
Algorithm 2 improves feasible point at each iteration and then bring a local optimum after finitely many iterations.

To find an initial feasible point for Algorithm 2, we consider the following problem:
\[
\max_{\mathbf{v}_D, \mathbf{v}_U, \rho > 0} \sum_{(i,j0) \in S_1} \{ f_i(V_D, V_U, 1/\rho) - \epsilon_i^{\min} \}
\]
(57)
\[
\tilde{f}_{i,j0}(V_D^E, V_U) \left( \rho - \epsilon_i^{\min} \right) \geq (41b) - (41c)
\]
which can be addressed by successively solving the following convex minimin program:
\[
\min_{\mathbf{v}_D, \mathbf{v}_U, \rho > 0} \sum_{(i,j0) \in S_1} \{ g_i^{(k)}(V_D, V_U) - \epsilon_i^{\min} \}
\]
(58)
upon reaching $r_{i,j_0}^{\min}$, $f_i^{(v)}(V_D^i, V_U^i, \alpha^{(\kappa)}) \geq r_{i,j_0}^{\min}$ and $E_{i,j_0}(V_D^i, V_U^i, 1/\rho^{(\kappa)}) \geq \epsilon^{\min}(i,j_0) \in S_1$.

For the system operating in HD mode, we apply the same transmission strategy as in Section II. Specifically, we consider the following problem:

$$
\max_{V_D, V_U, \rho} \frac{1}{2} \left[ \sum_{(i,j_0) \in S_1} \frac{1}{\rho} f_{i,j_0}(V_D, 0_U) + \sum_{i \in I} f_i(0_D, V_U, 1) \right] \quad \text{s.t.} \quad (39b) - (39e)
$$

(59a)

$$
\frac{1}{2}(E_{i,j_0}(V_D, 0_U, 1/\rho) + E_{i,j_0}(0_D, V_U, 1)) \geq \epsilon^{\min}(i,j_0) \in S_1,
$$

(59b)

$$
\frac{1}{2\rho} f_{i,j_0}(V_D, 0_U) \geq d^{\min}_{i,j_0}, \forall (i,j_0) \in S_1,
$$

(59c)

$$
\frac{1}{2} f_i(0_D, V_U, 1) \geq d^{\min}_{i}, \forall i \in I.
$$

(59d)

In (59), DLUs harvest energy for $(1-\alpha)$ of a 1/2 time slot during DL transmission and for the whole 1/2 time slot during UL transmission as formulated in (59b). The constraint (59b) can be written by

$$
\Xi_{i,j_0}(V_D, V_U, \rho) \geq \frac{2\epsilon_{i,j_0}(1 + \frac{1}{\rho} - 1)},
$$

(60)

for

$$
\Xi_{i,j_0}(V_D, V_U, \rho) \geq \frac{\langle \Phi_{i,j_0}(V_D, 0_U) \rangle + \langle \Phi_{i,j_0}(0_D, V_U) \rangle}{\rho - 1}\n$$

As $\Xi_{i,j_0}$ is convex, its minorant is its first-order approximation at $(V_D^{(\kappa)}, V_U^{(\kappa)}, \rho^{(\kappa)})$:

$$
\Xi^{(\kappa)}_{i,j_0}(V_D, V_U, \rho) = \phi_{i,j_0}^{(\kappa)}(V_D, 0_U) + \phi_{i,j_0}^{(\kappa)}(0_D, V_U) + \lambda_{i,j_0}^{(\kappa)}(V_D, V_U, \rho - 1),
$$

(61)

for $\lambda_{i,j_0}(\ldots)$ defined by (31) and $\phi_{i,j_0}(0_D, V_U)$ defined from (22) with both $V_U$ and $V_D^{(\kappa)}$ replaced by $0_U$.

The problem (39) thus can be addressed via a path-following procedure similar to Algorithm 2 where the following convex program is solved for $\kappa$-iteration:

$$
\max_{V_D, V_U, \rho} \frac{1}{2} \left[ \sum_{(i,j_0) \in S_1} g_{i,j_0}^{(\kappa)}(V_D, 0_U, \rho) + \sum_{i \in I} \Theta_i^{(\kappa)}(0_D, V_U, 1) \right] \quad \text{s.t.} \quad (39b) - (39e)
$$

(61a)

$$
\Xi^{(\kappa)}_{i,j_0}(V_D, V_U, \rho) \geq \frac{2\epsilon_{i,j_0}^{(\kappa)}}{\epsilon_{i,j_0}(1 + \frac{1}{\rho} - 1)},
$$

(61b)

$$
\Xi^{(\kappa)}_{i,j_0}(V_D, V_U, \rho) \geq \frac{\langle \Phi_{i,j_0}^{(\kappa)}(V_D, 0_U) \rangle + \langle \Phi_{i,j_0}^{(\kappa)}(0_D, V_U) \rangle}{\rho - 1}\n$$

(61)

$$
\frac{1}{2} g_{i,j_0}(V_D, 0_U, \rho) \geq d^{\min}_{i,j_0}, \forall (i,j_0) \in S_1,
$$

(61c)

$$
\frac{1}{2} \Theta_i^{(\kappa)}(0_D, V_U, 1) \geq d^{\min}_{i}, \forall i \in I,
$$

(61d)

where $g_{i,j_0}^{(\kappa)}(V_D, 0_U, \rho)$ is defined by (48) with both $V_U$ and $V_D^{(\kappa)}$ replaced by $0_U$, while $\Theta_i^{(\kappa)}(0_D, V_U, 0)$ is defined by (54) with both $V_D$ and $V_D^{(\kappa)}$ replaced by $0_D$ and both $\rho$ and $\rho^{(\kappa)}$ replaced by $1$.

IV. THROUGHPUT QOS CONSTRAINED ENERGY-HARVESTING OPTIMIZATION

We will justify numerically that TS is not only easier implemented but performs better than PS for FD EH-enabled MU MIMO networks. This motivates us to consider the following EH optimization with TS, which has not been previously considered at all:

$$
\max_{V_D, V_U, \alpha} P_3(V_D, 0_D) \triangleq \sum_{(i,j_0) \in S_1} E_{i,j_0}(V_D, V_U, \alpha) \quad \text{s.t.} \quad (39b) - (39g).
$$

(62)

By defining $\rho = 1/\alpha$, we firstly recast $E_{i,j_0}(V_D^E, V_U, 1/\rho)$ as

$$
E_{i,j_0}(V_D^E, V_U, 1/\rho) = \langle \Phi_{i,j_0}(V_D^E, V_U) \rangle - Q_{i,j_0}(V_D^E, V_U, \rho),
$$

(63)

where $Q_{i,j_0}(V_D^E, V_U, \rho) \triangleq \frac{1}{2} \langle \Phi_{i,j_0}(V_D^E, V_U) \rangle$ is a convex function. Recalling that $\phi_{i,j_0}^{(\kappa)}(V_D^{(\kappa)}, V_U)$ defined in (22) is a minorant of $\langle \Phi_{i,j_0}(V_D^{(\kappa)}, V_U) \rangle$, we can now address the nonconvex problem (62) by successively solving the following convex program at $\kappa$-iteration:

$$
\max_{V_D, V_U, \rho} \sum_{(i,j_0) \in S_1} \frac{1}{2} \left[ \langle \Phi_{i,j_0}(V_D^E, V_U) \rangle - Q_{i,j_0}(V_D^E, V_U, \rho) \right] \quad \text{s.t.} \quad (39c), (40), (55c), (55d), (55f), (55g).
$$

(64)

A path-following procedure similar to Algorithm 2 can be applied to solve (62).

For the system operating in HD mode, the same transmission strategy as in Section II is applied. Specifically, we consider the following problem:

$$
\max_{V_D, V_U, \rho} \sum_{(i,j_0) \in S_1} \frac{1}{2} (E_{i,j_0}(V_D^E, 0_U, 1/\rho) + E_{i,j_0}(0_D, V_U, 0)) \quad \text{s.t.} \quad (39c), (40), (39d), (39e), (59c), (59d).
$$

(65)

The problem (65) can be addressed via a path-following procedure similar to Algorithm 2 where the following convex program is solved for $\kappa$-iteration:

$$
\max_{V_D, V_U, \rho} \sum_{(i,j_0) \in S_1} \frac{1}{2} \left[ \langle \Phi_{i,j_0}(V_D^E, 0_U) \rangle - Q_{i,j_0}(V_D^E, 0_U, \rho) \right] \quad \text{s.t.} \quad (39c), (40), (39d), (39e), (61d), (61e),
$$

(66)

where $\phi_{i,j_0}^{(\kappa)}(V_D^E, 0_U) \langle \Phi_{i,j_0}(V_D^E, 0_U) \rangle$ is defined by (22) with both $V_U$ and $V_D^{(\kappa)}$ (both $V_D$ and $V_D^{(\kappa)}$, resp.) replaced by $0_D$ (both $0_D$, resp.).

Problems (55), (58), (61), (64) and (66) involve $n = 2(N_1d_1ID + N_1d_2IU) + 3$ scalar real decision variables and $m = ID + IU + 2I + 3$ quadratic constraints so its computational complexity is $O(n^3m^2.5 + m^3.5)$. 
is the angle-of-arrival, the angle-of-departure, respectively. In λ

H
of-sight (LOS) deterministic component and each element
K
are uniformly distributed within the cell of their serving BS.

Fig. 2. A three-cell network with 3 DLUs and 3 ULUs. DLUs are randomly
located on the circles with radius of r1 centered at their serving BS. ULUs
are uniformly distributed within the cell of their serving BS.

V. NUMERICAL RESULTS

In this simulation study, we use the example network in
Fig. 2 to study the total network throughput in the presence
of SI. The HD system is also implemented as a base line for
both time splitting mechanism and power splitting mechanism.
DLUs are randomly located on the circles with radius of
r1 = 20 m centered at their serving BSs whereas ULUs
are uniformly distributed within the cell of their serving BSs
whose radius are r2 = 40 m. There are two DLUs and
two ULUs within each cell. We set the path loss exponent
β = 4. For small-scale fading, we generate the channel
matrices H_{m,i,j_0} from BS m to UE (i,j_0), matrices H_{i,j_0,ℓ_0}
from ULU (i,ℓ_0) to DLU (i,j_0), matrices H_{m,ℓ_0,ℓ_1} from ULU
(m,ℓ_0) to BS i and matrices H^{B,i}_{m,i} from BS m to BS i using
the Rician fading model as follows:

\[ H = \sqrt{\frac{K_R}{1 + K_R}} H^{LOS} + \sqrt{\frac{1}{1 + K_R}} H^{NLOS}, \]  

where \( K_R = 10 \) dB is the Rician factor, \( H^{LOS} \) is the line-of-sight (LOS) deterministic component and each element
of Rayleigh fading component \( H^{NLOS} \) is the circularly-
symmetric complex Gaussian random variable \( \mathcal{CN}(0, 1) \). Here, we use the far-field uniform linear antenna array model [32] with

\[ H^{LOS} = \begin{bmatrix} \left[ 1, e^{j\theta_1}, e^{j2\theta_1}, \ldots, e^{j(N_r - 1)\theta_1} \right] \
\therefore, e^{j2\theta_1}, \ldots, e^{j(N_r - 1)\theta_1} \right] 
\end{bmatrix}^{H}, \]  

for \( \theta_r = \frac{2\pi d \sin(\phi_r)}{\lambda}, \theta_l = \frac{2\pi d \sin(\phi_l)}{\lambda}, \) where \( d = \lambda/2 \)
is the antenna spacing, \( \lambda \) is the carrier wavelength and \( \phi_r, \phi_l \)
is the angle-of-arrival, the angle-of-departure, respectively. In
our simulations, \( \phi_r \) and \( \phi_l \) are randomly generated between
0 and 2\( \pi \). Unless stated otherwise, the number of transmit
antennas and the number of receive antennas at a BS are set
as \( N_1 = N_2 = 4 \). The numbers of concurrent downlink data
streams and the numbers of concurrent uplink data streams
are equal and \( d_1 = d_2 = N_r \). To arrive at the final figures,
we run each simulation 100 times and average out the result.
In all simulations, we set \( P = 23 \) dB, \( P_i = 16 \) dB
\( i \in I, P_{i,j_0} = 10 \) dB \( \forall i,j_0 \in I \), \( \lambda = 16 \) dB, \( \sigma_i^2 = -90 \) dB, \( \sigma_i^2 = -90 \) dB, \( r_{\text{min}}^D = r_l^D = 1 \) bps/Hz and
\( r_{\text{min}}^R = r_l^R = U_{l,t} = 160 \) bps/Hz. We further assume that the required
harvested energies of all DLUs are the same and \( e_{\text{min}}^D = e_{\text{min}}^R \),
\( \forall (i, j_D) \). Unless stated otherwise, we set \( e_{\text{min}} = -20 \) dBm as
in [7], [33]. According to the current state-of-the-art-electronic
circuitry, the sensitivity level of a typical energy harvester is
around -20 dBm (0.01mW) [34], which means that we can
activate the EH circuitry with that much amount of received
power. The SI level \( \sigma_{SI}^2 \) is chosen within the range of
[\(-150, -90\)] dB 1 as in [14], [16], [26] where \( \sigma_{SI}^2 = -150 \)
dB represents the almost perfect SI cancellation.

A. Single cell network

Firstly, we consider the sum throughput maximization problem
and the total harvested energy in the single cell networks.
This will facilitate the analysis of the impact of SI to the
network performance since there is no intercell interference.
The network setting in Fig. 2 is used but only one cell is
considered.

Fig. 3 illustrates the comparison of total network throughput
between the power splitting mechanism and the time splitting
mechanism in both FD and HD systems. Though FD provides
a substantial improvement in comparison to HD in both power
splitting mechanism (25.8%) and time splitting mechanism
(26.1%) for \( N_r = 2 \) at \( \sigma_{SI}^2 = -150 \) dB. Note that we
cannot expect a FD system to achieve twice the throughput
of that is achieved by a HD system. This is because even
when the SI cancellation is perfect, DLUs in FD are still
vulnerable to the intracell interference from the ULUs of the
same cell. Moreover, DLUs and ULUs in HD are served with
more BS’ antennas, resulting in a larger spatial diversity.
Consequently, FD cannot double HD’s throughput even with
the almost perfect SI cancellation.

When we reduce the number of antennas at UEs from
\( N_r = 2 \) to \( N_r = 1 \), the total network throughput of FD is
significantly reduced by 42% for the time splitting mechanism
and by 41% for the power splitting mechanism at \( \sigma_{SI}^2 = -150 \) dB.
Notably, since UEs in FD are exposed to more sources
of interference than UEs in HD, reducing the number of antennas at UEs degrades the performance of FD more than
the counterpart of HD. Consequently, the improvement of FD
in comparison to HD reduces to 16% at \( \sigma_{SI}^2 = -150 \) dB for
both time splitting mechanism and power splitting mechanism.

Fig. 4 further illustrates how the total throughput is dis-
tributed into the downlink and uplink channels in the time
splitting mechanism. The behaviour of the power splitting
mechanism is similar and omitted here for brevity. With the

1At \( \sigma_{SI}^2 = -90 \) dB, if a BS transmits at full power (i.e. 16 dBW), the SI
power is 16 dB stronger than the background AWGN.
2\( N_r \) has been defined in the begining of section II as the number of antennas
of UEs (DLUs and ULUs).

\[ 1 \]
increase of $\sigma_{SI}^2$, the UL throughput consistently decreases. Moreover, since the UL transmission becomes less efficient, ULUs reduce their transmission power to reduce the interference toward DLUs. Consequently, a slight increase in FD DL throughput is observed as $\sigma_{SI}^2$ increases. Another note is that since the distance between ULU-DLU in small cell can be quite small due to the random deployment of ULUs and DLUs, DLUs’ throughput can be severely degraded by the interference from ULUs. In fact, the FD DL throughput at $\sigma_{SI}^2 = -150$ dB is only 10% less than the counterpart of HD.

To analyze the effect of energy harvesting constraint, we fix $N_r = 2, \sigma_{SI}^2 = -110$ dB and vary $e_{\text{min}}$. Fig. 5 illustrates a consistent decreasing trend of all schemes as $e_{\text{min}}$ increases. The time splitting scheme outperforms the power splitting scheme in the considered range of $e_{\text{min}}$ for both FD and HD. A similar conclusion can be drawn from Fig. 3. By using two different precoder matrices $V^I$ and $V^E$ for data transmission and energy transferring, the time splitting scheme can exploit the spatial diversity better than the power splitting scheme which only uses one type of precoder matrix for both purposes. Thus, the time splitting scheme is more efficient than the power splitting scheme in term of performance.

The comparison of maximum harvested energy of time splitting scheme in both FD and HD systems is studied in Fig. 6. Interestingly, in case of $N_r = 1$, FD roughly harvests as much as HD. The reason of this is two folds. Firstly, it has been reported in [16], [26], [35] that FD not always harness performance gain over HD if the distance between ULUs and DLUs are not large enough. Since we consider small cell networks with randomly deployed ULUs and DLUs, the ULU-DLU distance can be very small, which creates significant interference to DLUs. Secondly, with $N_r = 1$, DLUs can not exploit the spatial diversity to mitigate the interference from ULUs. Consequently, ULUs must reduce its transmit power to ensure the QoS at the DLUs, which lowers the amount of harvested energy at DLUs. In contrast, the results show that
FD harvests more energy than HD given that $\sigma_{SI}^2 \leq -90$ dB for $N_r = 2$. All this implies that having multiple antennas at UEs is important to combat with extra interferences in FD.

B. Three-cell network

Now, we consider the sum throughput maximization problem and the total harvested energy in the three-cell networks as depicted in Fig. 2. In this scenario, DLUs and BSs are exposed to additional intercell interferences. According to Fig. 7, FD now only provides a marginal improvement regarding HD in both power splitting scheme (11.7%) and time splitting scheme (11.8%) for $N_r = 2, \sigma_{SI}^2 = -150$ dB. For $N_r = 1, \sigma_{SI}^2 = -150$ dB, the improvement is even lower with 4.1% in case of the power splitting scheme and 4.4% in case of time splitting scheme. Therefore, FD can give marginal gains compared to HD in the multi-cell networks with high level of interference.

The effect of energy harvesting constraint to the network...
and HD systems in three-cell network. For \( N_r = 1 \), FD even
harvests lesser amount of energy than HD given \( \sigma_{SI}^2 > -150 \)
dB due to the increasing level of interference when compared
to a single-cell network. Similar to the single-cell network,
FD outperforms HD for \( \sigma_{SI}^2 \leq -90 \) dB if more antennas
are equipped at UEs (i.e. \( N_r = 2 \)). This observation again
emphasizes the importance of having multiple antenna at UEs
in FD to mitigate interference. Another note is that given
\( N_r = 2 \) the amount of energy harvested per cell in three-cell
networks (i.e. 10.09 dBm at \( \sigma_{SI}^2 = -150 \) dB) is much higher
than the harvested energy of single cell in Fig. 6 (i.e. 8.5 dBm
at \( \sigma_{SI}^2 = -150 \) dB), thanks to the extra energy harvested from
the intercell interference.

C. Convergence behaviour

Finally, the convergence behavior of the proposed Algorithm 1 is illustrated in Fig. 10. For brevity, we only present the
case of the three-cell network at \( \sigma_{SI}^2 = -110 \) dB and \( N_r = 2 \).
Fig. 10(a) plots the convergence of the objective functions of the sum throughput maximization problem for the time
splitting scheme and the power splitting scheme, whereas Fig. 10(b) plots the convergence of the objective function of the EH
maximization problem. As can be seen, the sum throughput maximization problem achieve 90\% of its final optimal value
within 40 iterations whereas the EH maximization problem needs 10 iterations. Table I shows the average number of iter-
ations required to solve each program. Note that each iteration of the proposed algorithms invokes a convex subproblem to
generate a new feasible point that is much higher
than the incumbent that is
as the initial point for the process
and the nonconvexity of the considered problems imply that
checking the global optimality of the computed solution is
both theoretically and practically prohibitive. Nevertheless, our
recent results in [9] and [10] for the particular multi-input
single output (MISO) case of the HD optimization problem
(29) show that both Algorithm 1 and Algorithm 2 are capable
delivering the global optimal solutions.

VI. Conclusion
We have proposed new optimal precoding designs for EH-enabled FD multicell MU-MIMO networks. Specifically, sum throughput maximization under throughput QoS constraints and EH constraints for energy-constrained devices under either TS or PS has been considered. The FD EH maximization problem under throughputs QoS constraints in TS has also been addressed. Toward this end, we have developed new path-following algorithms for their solution, which require a convex quadratic program for each iteration and are guaranteed to monotonically converge at least to a local optimum. Finally, we have demonstrated the merits of our proposed algorithms through extensive simulations. Note that an interesting topic for further research is this area is robust precoder/beamformer design in the presence of channel estimation errors.
