ABSTRACT: Rules for predicting anionic S_N2 displacement viability in furanose and furanoside sulfonates are presented. Recently, we published an update\(^1\) of the Richardson-Hough rules\(^2\) for predicting S\(_N2\) displacement viability in pyranoside sulfonates with charged nucleophiles. Here, we present a second set of rules for the rapid assessment of anionic S\(_N2\) displacement viability in furanose and furanoside O-sulfonates, and although the guidelines that we proffer do not cover every reaction possibility, they do allow the confident prediction of many outcomes, particularly when used with the detailed reaction survey that we have provided in the Supporting Information. The latter gives examples of the various types of furanoside/furanose secondary O-sulfonate that have so far been examined in the S\(_N2\) process.

Central to the successful development and future application of these rules is the new system we have devised for categorizing the different types of furanoside/furanose O-sulfonate. For this we employ the long established descriptors, \(\beta\) and \(\alpha\), to define upward- and downward-pointing \(\textit{exo}\)-heteroatom stereochemistry on a furanose/furanoside ring. Standard monosaccharide ring numbering is additionally employed to depict \(\textit{exo}\) substituent position. For the hypothetical furanoside 1, where three heteroatom groups are located on the top-side of the ring at carbons 1, 3 and 4, and a single substituent is present on the underside of the ring at C(2), the prefix \(\beta(1,3,4)-\alpha(2)\)-unambiguously defines its substitution pattern, while the configuration at C(1) determines \(\alpha/\beta\) primacy within the prefix. A suffix is also used to specify the type of O-sulfonate that is being displaced. It too is numbered to identify its position on the furanoside ring. Accordingly, structure 1 can be designated as a \(\beta(1,3,4)-\alpha(2)-\text{O2-tosylate}\), and glycoside 2 as an \(\alpha(1,2)-\beta(3,4)-\text{O2-triflate}\). By structurally classifying all of the main types of furanoside/furanose O-sulfonate in like fashion, and comparing their differing S\(_N2\) reactivity profiles, it is possible to formulate a general set of S\(_N2\) viability rules for the various classes of O-sulfonate that exist. These guidelines are adumbrated below, with the proviso that many other electronegative substituents, such as an N3 or F, will exert a similar electronic effect to a ring OR group when they are stationed in an identical position (see the Supporting Information).

Rule 1. \(\beta\)-Furanoside 2-O-sulfonates: (a) S\(_N2\) reactions are disfavored\(^3\)\(^-\)\(^7\) on the following \(\beta\)-furanoside 2-O-sulfonates:
The great reluctance with which these four classes of furanoside O-sulfonate engage in $S_{N}2$ displacement reactions can be ascribed to adverse steric and dipolar repulsions being encountered in the advancing $S_{N}2$ transition states (TSs) as they attempt to proceed towards product. While eqs 1-4 illustrate just a few of the vicinal repulsions encountered in the different $S_{N}2$ TSs, when in the $E_2$ conformation, similar opposing forces can be identified in the $S_{N}2$ TSs of many other readily accessed starting conformers. The situation can perhaps be most readily visualized by examining several different $S_{N}2$ TSs for $\beta(1,3,4)$-$\alpha(2)$-furanoside O2-sulfonates, and considering these as representative of the many possible for each of the four classes of O-sulfonate: In all cases, the combined depicted repulsions conspire to strongly disfavor or thwart successful $S_{N}2$ displacement, and the Vicinal Triflate Effect$^1$ can only help to a limited extent. Likewise, for furanose $\beta(1,4)$-$\alpha(2,3)$-O2-tosylate and mesylate displacements, strong steric hindrance and unfavorable dipolar repulsions are both apparent in many prospective $S_{N}2$ TSs in a wide range of conformers. For example:

Despite the Vicinal Triflate Effect$^1$ lowering adjacent fixed opposing C-O dipoles in $\beta(1,4)$-$\alpha(2,3)$-O2-triflates, to render the $S_{N}2$ process electronically viable for all nucleophiles, the anti-relationship between H(3) and the C(2)-OTf makes the latter highly susceptible to undergoing E2 elimination even with moderately basic nucleophiles.

**Rule 2. $\alpha$-Furanoside 2-O-sulfonates:** (a) $S_{N}2$ displacements on $\alpha(1,2,3)$-$\beta(4)$-O2-tosylates and mesylates are possible, but are generally disfavored and fairly low yielding when attempted (eq 7).$^5b$ Displacements on their $\alpha(1,2)$-$\beta(3,4)$-O2-tosylate and mesylate cousins are also likely to be problematical (eq 8); see the SI for our explanation.

(b) By way of contrast, $S_{N}2$ reactions are usually successful when conducted on the corresponding $\alpha(1,2,3)$-$\beta(4)$-O2-triflates and -O2-imidazolesulfonates (eq 9)$^9,12,13$ and $\alpha(1,2)$-$\beta(3,4)$-O2-triflates and -O2-imidazolesulfonates (eq 10),$^7,14-16$ and
α(1,3)-β(2,4)-O2-triflates (eq 11) due to the dipole-lowering effects of these two leaving groups on adjacent OR or other electronegative groups.

Rule 3. 1,2-O-Isopropylidened α-Furanose 3-O-sulfonates. For 1,2-O-isopropylidened furanose 3-O-sulfonates, the descriptor “1,2-O-isopropylidene” is also introduced into the O-sulfonate classification system. Accordingly:

(a) (i) S_N2 displacements on α(1,2)-β(3,4)-1,2-O-isopropylidene-O3-tosylates and mesylates are usually counteracted sterically by the 1,2-O-acetal, and electronically by the opposing repulsive C(2)-O(2) fixed dipole, which collectively hamper attainment of many S_N2 TSs (eq 12). Despite this, such substitutions can occasionally be effectuated with good nucleophiles such as N3- or AcS-, but frequently they are accompanied by E2 elimination.18-26 In many cases, as well, such alkene by-products are difficult to separate from the desired S_N2 products. (ii) While S_N2 displacements on the analogous 3-O-triflates do typically proceed with much greater facility,27-34 due to the Vicinal Triflate Effect (eq 13), and likewise 3-O-imidazolesulfonates35 (due to analogous vicinal dipole-lowering effects associated with imidazolesulfonates and their imidazole-displaced sulfonate intermediates), still, C(3)/C(4)-elimination is a common problem for more basic nucleophiles.

Rule 4. 2,3-O-Isopropylidene Ketofuranose 4-O-Sulfonates. Current evidence suggests that S_N2 displacements on ketofuranoside β(2,3,5)-α(4)-2,3-isopropylidene O4-halosulfonates, tosylates and mesylates are strongly disfavored stereo-electronically (eq 18). Displacements on their β(2,3,4,5)-O4-sulfonate counterparts are viable, however (eq 19).

Rule 5. Furanoside 3-O-sulfonates. (a) While S_N2 processes are usually difficult to effect on β(1,2,3,4)-O3-tosylates and mesylates, they can occasionally be performed in modest yield with very good nucleophiles (eq 20), but once more, C(2)/C(3)-elimination can interfere detrimentally.
The experimental data that underpins these rules can be found tabulated in the Supporting Information. This material is available free of charge via the Internet at http://pubs.acs.org

Supporting Information

(b) $\mathbf{S_2}$ displacements on $(\alpha,1,4)\alpha(2,3)$-$O_3$-tosylates and mesylates,52,53 and $(\alpha,1)\alpha(2,3,4)$-$O_3$-tosylates and mesylates generally proceed in acceptable yield (eqs 21, 22).54

Rule 6. Furanoside 5-sulfonates. When primary, these always displace readily. However, when secondary, as in hexofuranosides, often more forcing conditions are required to effect $\mathbf{S_2}$ displacement, and such reactions usually proceed without neighboring-group participation if an O-ester group is present at O(6).

Rule 7. Hexofuranoside 6-O-sulfonates. Being primary, these generally occur in good yield for all 6-O-sulfonates.

Rule 8. Hexofuranoside 6-O-sulfonates. $\mathbf{S_2}$ displacements on C(1)-OTf and C(1)-OMs derivatives are usually difficult due to the TsSs encountering adverse dipolar repulsions from the two C(2)-O atoms, and steric hindrance from the neopentyllic center. Even so, the Vicinal Triflate Effect1 can allow these $\mathbf{S_2}$ displacements to proceed with 1-OTf derivatives.
