KEYWORDS USP7 ubiquitination deubiquitinase HAUSP p53 Mdm2 proteasome ubiquitin

ABSTRACT: Ubiquitin specific protease 7 (USP7, HAUSP) has become an attractive target in drug discovery due to the role it plays in modulating Mdm2 levels and consequently p53. Increasing interest in USP7 is emerging due to its potential involvement in oncogenic pathways as well as possible roles in both metabolic and immune disorders in addition to viral infections. Potent, novel and selective inhibitors of USP7 have been developed using both rational and structure-guided design enabled by high resolution co-crystallography. Initial hits were identified via fragment-based screening, scaffold-hopping and hybridization exercises. Two distinct sub-series are described along with associated SAR trends, as are initial efforts aimed at developing compounds suitable for in vivo experiments. Overall these discoveries will enable further research into the wider biological role of USP7.

The process of protein ubiquitination is a central tenet of the ubiquitin proteasome system (UPS) and is crucial in many fundamental cellular processes such as proteolysis, cell-cycle control, DNA repair and apoptosis.1,2 The importance of this pathway in controlling such key cellular processes cannot be understated and increasing evidence linking the UPS to human diseases such as cancer1 and neurodegenerative disorders4 is emerging. The approved proteasome inhibitor Velcade® (bortezomib) has demonstrated that the UPS is a viable target for small molecule therapeutic intervention.5 Targeting the UPS upstream of the proteasome may therefore yield new opportunities for targeted therapeutics with improved specificity and toxicity profiles.

Ubiquitination is a post-translational modification via covalent attachment of the 76 amino acid protein ubiquitin to lysine side chains of target substrates. This elegant and complex molecular “tagging” of target proteins is effected by E1 (activating), E2 (conjugating) and E3 (ligase) enzymes and has multiple functions including targeted substrate degradation, activation for further processing and cellular localization.6

The process of ubiquitination is reversed by deubiquitinase enzymes (DUBs) of which there are around 100 encoded by human genes.7 Ubiquitin specific proteases (USPs) are cysteine proteases that comprise the largest (>50) sub-class of DUBs and are gaining interest as an emerging target class for pharmaceutical intervention.8 There are sparingly few validated small molecule inhibitors reported for USPs and as such there is an acute need to develop robust probe compounds for use in deciphering the biological pathways associated with the USP target class. USP7 represents one of the most studied USPs from a target class that remains largely underexplored and as such has gained attention in recent years due to its association with cancer.9,10 USP7 is involved in the regulation of the stability of the tumor suppressor p53 via deubiquitination of the oncoprotein Mdm2.11 USP7 mediated stabilization of Mdm2 reduces cellular p53 and may protect damaged cells from apoptosis. In addition, USP7 has also been implicated in the regulation of several other key signaling proteins linked to tumorigenesis.12-17 Targeting USP7 with small molecules has therefore been of great interest over recent years but has until recently met with limited success due to several factors including poor compound specificity, low potency and/or poor compound properties.18 Very recent publications have described the characterization of more drug-like USP7 inhibitors that further reinforce the potential druggability of this target class.19-22

Recently we published the detailed in vitro biological profiling and co-crystal structures of highly potent non-covalent USP7 inhibitors in a variety of biochemical and cellular assays.22 These compounds have proven to be highly valuable tools for interrogating the complex biology of USP7 and will enable further studies aimed at delineating USP7 biology. Herein we describe the hit-finding and medicinal chemistry efforts towards these tool compounds, summarize the SAR and outline the identification of a novel sub-series of USP7 inhibitors. The binding mode (by way of X-ray co-crystallography) of this sub-series is highlighted as is the pharmacokinetic profiling of early leads from both series.

Our USP7 hit-finding strategy involved initial fragment screening using surface plasmon resonance (SPR) coupled with
the parallel in vitro benchmarking of published USP7 inhibitors. Briefly, SPR screening of 1.9k fragments versus immobilized USP7 catalytic domain afforded a range of primary USP7 binding fragments including thieno-pyrimidinone 1 (Figure 1).

Figure 1. Primary USP7 SPR binding fragment 1.

Compound 1 was found to be a high ligand efficiency USP7 binder (LE = 0.47) with an SPR equilibrium binding constant ($K_D$) of 471 µM (Figure S1, SI). Binding of compound 1 to USP7 was subsequently confirmed by orthogonal techniques (ligand observed STD, CPMG and WaterLOGSY NMR experiments) (Figure S2, SI). Further profiling revealed that 1 had excellent aqueous kinetic solubility (>200 µM) and was free from redox cycling activity – a liability that has the potential to lead to false positive readouts in biochemical assays. 1 and analogues thereof were then incorporated into our wider USP7 medicinal chemistry program which involved scaffold-hopping to other fused 5-membered ring pyrimidinones. A range of analogues derived by scaffold-hopping to other fused 5-membered ring pyrimidinones were explored in parallel to substitution on the bicyclic thieno-pyrimidinone ring, our attention turned to SAR analysis of the phenethylamide moiety. During the course of our studies a key breakthrough was the observation that methyl substitution at the benzylic position of compounds such as 11 led to a significant (>40-fold) increase in USP7 potency. This large increase in potency was fully dependent on the stereochemistry of the newly installed chiral methyl group as exemplified by compounds 16 and ent-16 (Figure 2).

Compounds 2 and 3 were deemed suitable for further SAR studies due to their reasonable ligand efficiencies (LE) and favorable physicochemical properties. A range of analogues derived by scaffold-hopping to other fused 5-membered ring pyrimidinones were explored in parallel to substitution on the bicyclic pyrimidinone core (Table 2). Furano, pyrazolo and thiazolo-pyrimidinone analogues 4-8 were largely equipotent with thieno-pyrimidinones 2 and 3. Substitution of a lipophilic bromine atom at either the C-5 or C-6 positions of the thiophene ring in compounds 9 and 10 did not lead to marked USP7 potency gains whereas substitution at the C-7 position led to an appreciable (ca. 5-fold) potency enhancement as demonstrated by compound 11. Pleasingly, substitution at this position with other lipophilic groups such as cyclopropyl 12, alkynyl 13 and phenyl 14 also afforded noticeable potency gains versus the non-substituted analogue 3. Substitution at the 2-position of the pyrimidinone ring with a methyl substituent was not tolerated (compound 15).

With potency gains of ca. 5-10 fold attainable via modification of the bicyclic thienopyrimidinone ring, our attention now in hand we initiated co-crystallization studies with the catalytic domain (amino acids 207-560) of USP7. We subsequently obtained a 2.3 Å resolution X-ray co-crystal structure of compound 16 and USP7 that revealed the ligand bound in the catalytic cleft between the β-sheet of the palm subdomain and the helices of the thumb subdomain. Removal of key ligand hydrogen-bonding heteroatoms (such as the amide carbonyl, tertiary alcohol or pyrimidinone N-1 nitrogen from the bicyclic core) was highly deleterious to USP7 binding (data not shown) highlighting the importance of each individual interaction.

Aided by the X-ray co-crystal structure, we were able to use structure-based design to further optimize our USP7 inhibitors with the aim of enhancing target affinity (whilst retaining favorable physicochemical properties). Our initial focus centered on the thiophene ring of compound 16 which contains a bromine substituent at C-7 that is orientated towards the protein surface with a high degree of solvent exposure and was thus viewed as a promising vector for new analogue design and optimization. Encouragingly, scaffold-hopping from the thienopyrimidinone core of compound 16 to the more drug-like N-methyl pyrazolo-pyrimidine core (compound 17, Table 3) not only lowered overall lipophilicity (logD7.4 1.5 vs 2.3) but was
also not detrimental to USP7 activity. Given this result, we decided to concentrate our efforts on the pyrazolo-pyrimidinone core and a summary of the SAR is presented in Table 3.

Our strategy (guided by docking studies using the co-crystal structure) was centered on targeting both hydrogen-bond and hydrophobic interactions via selective substitution at the pyrazole C-3 position. Incorporation of alkynyl, alkyl or isopropyl substituents at the C-3 position (compounds 18-21) did not prove fruitful, however, when pyrazole or phenyl groups were incorporated at this position a ca. 10-fold increase in USP7 potency was observed (e.g. compound 23, IC50 0.03 µM). This marked increase in potency may involve a CH-π interaction between the pendant pyrazole or phenyl groups of 22 or 23 and Gln351 as postulated in the published co-crystal structure.22 Addition of an ortho-fluoro group to the pendant phenyl in compound 23 led to a slight decrease in potency (compound 24, IC50 0.09 µM) in contrast to ortho-anilino substituted compound 25 which was around 40-fold less potent than 23 – possibly due to the larger ortho-NH2 substituent increasing the dihedral angle between the phenyl ring and the core, causing an unfavorable steric clash between the phenyl ring and the protein surface. Addition of hydrogen-bond acceptors and donors at the meta and para positions on the pendant phenyl group (compounds 26-30) largely maintained potency in relation to 23 with the exception of compound 31 which showed a marked decrease in potency, most likely due to the added steric bulk of the morpholine group. Interestingly, the para-carboxamide or benzyl alcohol groups in compounds 22 and 33 did not lead to potency increases whereas the para-benzyl amine moiety in compound 34 (IC50 = 6 nM) provided a ca. 5-fold increase in potency over compound 23. The (S)-Me enantiomer of 34 was found to have an IC50 of 2.4 µM, representing a 400-fold decrease in USP7 potency.23

In addition to identifying the promising pyrazolo-pyrimidinones described above, we also investigated how truncation of the bicyclic core would affect USP7 binding. Hence, a series of monocyclic pyrimidinones such as compound 35 were synthesized (Table 4). Although only moderately active, compound 35 (IC50 = 23 µM) represented a promising and ligand efficient (LE = 0.25) starting point for further analogue work with respect to its low molecular weight and logD7.4 (355 and 0.9 respectively). A range of analogues were subsequently prepared substituted at the C-6 position of the pyrimidinone ring with representative examples shown in Table 4.

Overall SAR at this position suggested that substitution was largely beneficial for USP7 potency. Substitution with simple amines such as methylamine or aniline (compounds 36 and 37) increased potency by 5 to 10-fold versus the unsubstituted analogue 35. Switching the –NH linker in compound 37 to –CH3 in compound 38 resulted in a significant USP7 potency drop-off (IC50 = 1.9 µM versus 90 µM). Potency was regained when the methylene phenyl linker in compound 38 was switched to an alkynyl linker group (compound 39, IC50 = 2.8 µM). Ethylenediamine analogue 40 (IC50 = 0.12 µM) represented a >190-fold improvement in USP7 biochemical potency over the simple analogue 35 suggestive of new hydrogen-bonding interactions. Indeed, close analogues of compound 40 in which the hydrogen-bonding interaction potential of the ethylenediamine side-chain was modified led to decreases in potency (compounds 41-45). Pyrrolidine analogue 46 represented the first
sub-100 nM compound from this series and suggested that the basic pyrrolidine nitrogen was making a critical hydrogen-bond with USP7.

Intrigued by the observed SAR in which the precise nature of the side-chain linker and the pK_a of the amine both seemed crucial, molecular modelling suggested that a close interaction between the protonated amine of 46 and Asp295 was potentially achievable. This was subsequently confirmed via a high resolution (2.2 Å) X-ray co-crystal structure of compound 46 bound to USP7 that demonstrates a similar binding mode to that of compound 16 reported previously (Figures 3A and 3B).

In addition to the important hydrogen bond interaction network observed previously with 16, we also observed the postulated additional hydrogen bond between the protonated nitrogen of the pyrrolidine side-chain of 46 and Asp295 demonstrating a unique bidentate binding interaction pattern with Asp295 which had not been previously reported. This extra interaction appears to be crucial for improving affinity within the monocyclic series. As with compound 16, the amide carbonyl in 46 interacts with the Tyr465 hydroxyl group and the ligand tertiary alcohol and forms hydrogen bonds with both Asp295 and Val296. With regards to the pyrimidine ring of 46, the carbonyl oxygen atom forms a hydrogen bond with the backbone NH of Phe409 whereas the N-4 ring atom forms a hydrogen bond with Gln297 effectively stabilizing the monocyclic ring with interactions above and below the ring system (Figure 3A). The folded bioactive conformation of the phenethylamide side chain of 46 may partly be induced by allylic 1,3-strain between the benzyl CH and the phenyl ring as well as stabilization via a CH-π intramolecular interaction between the piperidine C-3 axial hydrogen and the phenyl ring. These intramolecular conformational drivers may in part be responsible for inducing binding site side-chain movements that create the overall binding pocket that accommodates this portion of the ligand. The resulting conformation is stabilized by a cation-π interaction between Lys420 and the ligand phenyl ring in addition to an edge-to-face π-π interaction with Phe409. Additional contacts between the phenethylamide methylene hydrogen atoms of 46 and the π system of His461 may also contribute to overall binding efficiency.

With highly potent USP7 inhibitors (from two distinct sub-series) such as 34 and 46 in hand, we performed extensive in vitro profiling and demonstrated that 34 shows potent target engagement of endogenous USP7 in cells as well as excellent selectivity for USP7 in panels of deubiquitinases, proteases and kinases. In addition, we also identified cancer cell lines that are hyper-sensitive to our USP7 inhibitors. Similar to compound 34, monocyclic analogue 46 shows excellent selectivity versus a panel of USPs (n = 21) when screened at a fixed concentration of 10 µM as well as potent intracellular USP7 target engagement (EC_{50} = 0.32 µM) in cells (Figures 4A and 4B).

In parallel to the in-depth cellular profiling outlined above, potent compounds were assessed in a range of in vitro assays in order to determine their suitability for in vivo studies. Generally, non-basic analogues were unstable in both human and mouse liver microsomes and had poor caco-2 permeability if they contained >1 hydrogen bond donor (HBD), thus precluding them from in vivo PK studies (e.g. compounds 23 and 33, Table 5). Likewise, benzyl amine 34 was found to have high in vitro metabolic turnover in both human and mouse liver microsomes (with predicted hepatic clearances of 18 mL/min/kg and 62 mL/min/kg respectively), whereas monocycle 46 had moderate metabolic stability in human and mouse liver microsomes (11 mL/min/kg and 34 mL/min/kg respectively). The aqueous kinetic solubility of both 34 and 46 was high (KSol > 190 µM) but the caco-2 A:B permeability of each at pH 6.5 was found to be low (P_{app} < 0.3 x 10^{-6} cm/s) limiting their potential for oral dosing. The low predicted in vivo hepatic stability of
the highly potent benzylic amine 34 encouraged us to carry out further chemical optimization in order to identify compounds with improved metabolic stability to facilitate in vivo proof-of-concept studies. As part of the chemistry program aimed at improving metabolic stability of compound 34, trifluoromethyl analogue 47 (Figure S3, SI) was prepared via an asymmetric hydrogenation route described previously.22

Table notes: See Supporting Information for assay conditions. HLM/MLM units: mL/min/kg. KSol units: µM. Caco-2 units: 10⁻⁶ cm/s

Compound 47 was found to have improved in vitro microsomal stability in both human and mouse microsomes compared to compound 34 (HLM CL_s 7 mL/min/kg vs 18 mL/min/kg and MLM CL_s 28 mL/min/kg vs 62 mL/min/kg) (Table 5). Furthermore, 47 largely maintained USP7 biochemical potency when contrasted with methyl analogue 34 (IC₅₀ = 22 nM vs 6 nM).

The pharmacokinetic profiles of compounds 46 and 47 were subsequently assessed in male CD-1 mice (Table 6). As expected from their low caco-2 permeabilities (A:B P_app < 0.3 x 10⁻⁶ cm/s) both compounds exhibited poor oral bioavailability (F < 1%). However, when dosed intraperitoneally (i.p.) both compounds exhibited reasonable bioavailability (F = 44% and 64% for 46 and 47 respectively). Volume of distribution for each compound was low (Vss ≤ 1 L/kg), in line with their low lipophilicities (logD₇.₄ ≤ 0). Compound 46 demonstrated low plasma clearance (CL = 13 mL/min/kg) whereas compound 47 had moderate clearance (CL = 32 mL/min/kg). Further optimization studies aimed at improving PK profiles based on these encouraging preliminary in vivo results are underway and will be reported in due course.

In conclusion, we have identified and optimized highly potent USP7 inhibitors based on two different core chemotypes. Key compounds have a well understood mode of binding as evidenced by the high resolution co-crystal structures obtained. These USP7 inhibitors have been highly valuable in validating the druggability of USP7 as well as enabling studies towards a deeper understanding of the underlying biology of USP7 and its potential as a therapeutic target. Efforts are continuing towards the further development of these inhibitors into compounds suitable for in vivo proof-of-concept studies.

1. Materials and reagents:

Common organic solvents that were used in reactions (e.g. THF, DMF, DCM, and methanol) were purchased anhydrous from Sigma-Aldrich® in Sure/Seal™ bottles and were handled appropriately under nitrogen. Water was deionised using an Elga PURELAB Option-Q. All other solvents used (i.e. for work-up procedures and purification) were generally HPLC grade and were used as supplied from various commercial sources. Unless otherwise stated, all starting materials used were purchased from commercial suppliers and used as supplied.

For assay purposes, all reagents and chemicals were purchased from Sigma-Aldrich® unless otherwise stated. All inhibitors were prepared as 10 mM DMSO stocks for cell culture experiments and stored in a controlled environment using the MultiPod system. CellTiter-Glo® was purchased from Promega (#G7571). The ubiquitin-propargylamine (Ub-PA) probe was purchased from UbiQ (#UbiQ-057). Unless otherwise stated, all other reagents were obtained from commercial sources and used without further purification.

General Experimental Conditions

Microwave synthesis
Microwave experiments were carried out using a Biotage Initiator™ Eight system or a CEM Discover™/Explorer24™
system controlled by Synergy 1.5 software. Both machines give good reproducibility and control at temperature ranges
from 60-250 °C and pressures of up to a maximum of 20 bar.

Flash chromatography
Purification of compounds by flash chromatography was achieved using a Biotage Isolera Four system. Unless other-
wise stated, Biotage KP-Sil SNAP cartridge columns (10-340 g) were used along with the stated solvent system and an
appropriate solvent gradient depending on compound polarity. In the case of more polar and basic compounds, Biotage
KP-NH SNAP cartridge columns (11 g) were used.

NMR spectroscopy
$^1$H NMR spectra were recorded at ambient temperature using a Bruker Avance (300 MHz), Bruker Avance III (400
MHz) or Bruker Ascend (500 MHz) spectrometer. All chemical shifts (δ) are expressed in ppm. Residual solvent signals
were used as an internal standard and the characteristic solvent peaks were corrected to the reference data outlined in J.
Org. Chem., 1997, 62, p7512-7515; in other cases, NMR solvents contained tetramethylsilane, which was used as an
internal standard.

Preparative High Pressure Liquid Chromatography
Method A: This system consisted of an Agilent Technologies 6120 single quadrupole mass spectrometer linked to an
Agilent Technologies 1200 Preparative LC system with multiple wavelength detector and autosampler. The mass spec-
trometer used a multimode ionization source (electrospray and atmospheric pressure chemical ionizations) operating in
positive and negative ion mode. Fraction collection was mass-triggered (multimode positive and negative ion). Purification experiments, unless otherwise stated, were performed under basic conditions at an appropriate solvent gradient that was typically determined by the retention time found using the LCMS method. In cases where the basic conditions were unsuccessful, acidic conditions were employed.

**Basic conditions:** LC Column: Waters XBridge™ Prep C18 5 μm OBD TM 19 x 50 mm column at rt. Mobile phase: A) 0.1% (v/v) ammonium hydroxide in water; B) 0.1% (v/v) ammonium hydroxide in 95:5, acetonitrile/water. Total experiment time was ca. 10 min and an example method is given:

**Method B:** This system consisted of a Waters Autopurification HPLC/MS, with a Gemini NX-C18 column from Phenomenex, 5 μm, 50 mm x 30 mm i.d., running at a flow rate of 60 mL/min, 25 °C with UV diode array detection (210–400 nm) and mass-directed collection. A typical gradient was 5-50% HPLC grade acetonitrile (mobile phase B) in HPLC grade water + 0.1% (v/v) ammonia solution (mobile phase A) over 10 min, or modified as necessary. The mass spectrometer used was a Waters Micromass ZQ2000 spectrometer, operating in positive or negative ion electrospray ionisation modes, with a molecular weight scan range of 150 to 1000.

The pure fractions were combined and concentrated using a Genevac EZ-2 Elite, unless stated otherwise.

**Final compound purity analysis**

The purity of final compounds was assessed by LCMS and 1H NMR. The HPLC purity of each compound was measured using the method stated compared to a blank.

**High Resolution Mass Spec**

High resolution mass spectra were acquired on a Thermo ScientificLTQ Orbitrap XL spectrometer at the EPSRC UK National Mass Spectrometry Facility (University of Swansea).

**General procedures**

**General procedure 1: Epoxide opening with a pyrimidinone**

A suspension of the pyrimidinone (1 equiv.), epoxide (1-3 equiv.) and Cs2CO3 (1-3 equiv.) in DMF were heated at 80 °C for 10-24 h. The reaction was allowed to cool to rt, saturated NH4Cl(aq) was added and the resulting mixture was extracted with DCM (x3) using a Biotage phase separator. The combined organic phases were concentrated under reduced pressure and the residue was purified by flash chromatography (Biotage KP-Sil and KP-NH, 0-100% EtOAc in cyclohexane or PE, then 0-30% MeOH in EtOAc) to give the product.

**General procedure 2: N-Boc deprotection**

A solution of the N-Boc piperidine in DCM/TFA was stirred for 1-24 h at rt before being concentrated under reduced pressure. The residue was then dissolved in triethylamine and DCM before being purified by flash chromatography
General procedure 3: EDC coupling
A solution of amine (1 equiv.), carboxylic acid (1 equiv.) and EDC (3 equiv.) was stirred in (DCM) for 1-24 h at rt. The reaction was quenched by the addition of water and the resulting mixture was extracted with DCM (x3) using a Biotage phase separator. The combined organic phases were concentrated under reduced pressure and the residue was purified by flash chromatography (Biotage KP-Sil and KP-NH, 0-100% EtOAc in cyclohexane or PE, then 0-30% MeOH in EtOAc) to give the product.

General procedure 4: HATU coupling in DCM
To a suspension of the amine (1 equiv.), carboxylic acid (1-1.5 equiv.) and HATU (1-1.5 equiv.) in DCM was added DIPEA (1-4 equiv.). The reaction was stirred for 1-24 h at rt before being quenched by the addition of saturated NaHCO₃(aq) and the resulting mixture was extracted with DCM (x3) using a Biotage phase separator. The combined organic phases were concentrated under reduced pressure and the residue was purified by flash chromatography (Biotage KP-Sil and KP-NH, 0-100% EtOAc in cyclohexane or PE, then 0-30% MeOH in EtOAc) to give the product.

General procedure 5: Suzuki-Miyaura coupling
A reaction tube was charged with a mixture of the bromide (1 equiv.), the organoboron reagent (1-3 equiv.), a Pd catalyst (0.05-0.1 equiv.) and an inorganic base (2-5 equiv.) in 1,4-dioxane/water and the O₂ was removed by evacuating and refilling with N₂ three times or by bubbling N₂ through the mixture before the reaction tube was sealed. The reaction was heated under the indicated conditions for the indicated time before being cooled to rt and saturated NH₄Cl(aq) added. The resulting mixture was extracted with DCM (x3) using a Biotage phase separator. The combined organic phases were concentrated under reduced pressure and the residue was purified by flash chromatography (Biotage KP-Sil and KP-NH, 0-100% EtOAc in cyclohexane or PE, then 0-30% MeOH in EtOAc) to give the product.

General procedure 6: Sonagashira coupling
A reaction tube was charged with the bromide (1 equiv.), a Cu catalyst (0.2-0.4 equiv.) and a Pd catalyst (0.1-0.2 equiv.) and then evacuated and refilled with N₂ three times. To this was added toluene, triethylamine (20-40 equiv.) and the alkyne (1-4 equiv.) before the mixture was again evacuated and refilled with N₂ three times. The reaction tube was sealed and the reaction was heated under the indicated conditions for the indicated time. The reaction was cooled to rt and quenched by the addition of saturated NH₄Cl(aq). The mixture was extracted with DCM (x3) using a Biotage phase separator. The combined organic phases were concentrated under reduced pressure and the residue was purified by flash chromatography (Biotage KP-Sil and KP-NH, 0-100% EtOAc in cyclohexane or PE, then 0-30% MeOH in EtOAc) to give the product.

3. USP7 surface plasmon resonance (SPR)

Fragment Library Screening:

SPR fragment library screening was performed by Beactica (Sweden) using Biacore 4000, S51 and T200 instruments (GE Healthcare/Biacore, Uppsala, Sweden). USP7 (His6-USP7CD (HAUSP cat domain), catalytic domain, aa 213-548, Boston Biochem, Lot # DBCW0111101) was immobilized by amine coupling using materials provided by GE Healthcare. The protein was prepared as a 0.1–0.2 mg/mL solution in coupling buffer (USP7: 50 mM acetate pH 5.5 supplemented with 2 mM DTT, 0.5 mM EDTA) and injected for 5 min over activated surfaces (50 mM N-hydroxysuccinimide, 200 mM N-ethyl-N'-((dimethylamino)propyl)carbodiimide) of CM7 or CM5 chips. The surfaces were subsequently deactivated by 1 M ethanolamine, pH 8.0.

Compound characterization: All interaction experiments were performed at 25 °C. Experiments were conducted in HBS buffer (10 mM HEPES, pH 7.4, 150 mM NaCl), supplemented with 0.05% Pluronic 127, 2 mM DTT, 0.5 mM EDTA and 5% (v/v) DMSO (all Sigma). The test compounds were diluted in the running buffer in two- or three-fold

4. USP7 NMR-binding studies:

Human USP7 catalytic domain (amino acids 208-555, Crelux GmbH) was delivered in PBS (137 mM NaCl, 2.7 mM
KCl, 1 mM NaH2PO4/Na2HPO4), pH 7.4 at a concentration of 13.9 mg/mL (331 μM). The protein was cloned and
expressed in E. coli

Reference 1H spectrum for compound 1 was collected at 1 mM concentration, formulated in PBS buffer identical to
that the protein was supplied in. The compound tested negative for self-aggregation using the WaterLOGSY pulse se-
quence with no macroscopically visible precipitate or diminished signals in the proton spectrum. Compound 1 was in-
cluded in a cocktail of other compounds, including a positive and negative control. The cocktail was comprised of 10
μM USP7 and a total of 6 compounds at a concentration of 200 μM each, resulting in a 1:20 USP7:compound ratio. Each
cocktail was subjected to a trio of 1H, ligand-observed experiments, namely saturation transfer difference (STD), Carr-
Purcell-Meiboom-Gill (CPMG) T2, and WaterLOGSY experiments.

NMR Hardware and Processing: All experiments were performed in-house on a 500 MHz Bruker AVANCE spectrom-
eter equipped with TCI Cryoprobe, using standard pulse programs included in Bruker’s experiment library. Spectra were
collected at 25 °C, and processed using Bruker’s TopSpin software program.

5. Biochemical and cellular assays:

The USP7 biochemical assay was performed using materials and conditions outlined in reference 1.

Target Engagement Assay in HCT116 Cells

HCT116 cells were treated with vehicle (DMSO) or USP7 inhibitor for 2 h. Following incubation, cells were washed
extensively with 1 x PBS and harvested in TE lysis buffer containing 50 mM TRIS-HCl (pH7.4), 150 mM NaCl, 5 mM
MgCl2, 0.5 mM EDTA, 0.5% NP40, 10% Glycerol, 2 mM DTT and clarified cell lysates (40 μg) incubated with the
ubiquitin-propargylamine probe (Ub-PA; 8 μg/ml final concentration) in assay buffer containing 50 mM TRIS-HCl
(pH7.6), 5 mM MgCl2, 250 mM Sucrose, 0.5 mM EDTA, 2 mM DTT for 30 min. The reaction was terminated by the
addition of LDS sample buffer (Life Technologies) and heated to 70 °C. Samples were then analyzed by western blotting
using the Cell Signalling anti-USP7 Ab (#4833; 1/1000 dilution). EC50 values were determined upon densitometry anal-
ysis. Band intensities were quantified using ImageJ software where the upper bands (USP7-Ub) and lower bands (USP7)
were calculated as a percentage of the corresponding DMSO controls (+/+ Ub-PA) and values were then normali-
ed to the sum of the lower and upper bands for each concentration.
6. DUB selectivity assay on compound 46:
Selectivity assays were performed against all USPs included in the DUBprofiler™ panel (Ubiquigent Ltd). Screening was performed at a fixed inhibitor concentration of 10 μM. Data generated is displayed as a percentage inhibition of total enzyme activity for each enzyme. Under the conditions of this screen, 46 exhibited an IC$_{50}$ value of 140 ± 22 nM. Data reported as the mean of 2 independent experiments.

7. Protein production, crystallization, data collection and structure determination:
The USP7 catalytic domain (residues 207-560), genetically fused with a C-terminal hexa-histidine tag, was expressed in E.coli. BL21 cells were transformed with the corresponding expression plasmid and grown in Terrific broth (TB) and protein expression induced with 0.25 mM IPTG overnight at 16°C. After harvesting by centrifugation, cell pellets were resuspended in Lysis Buffer (40 mM TRIS-HCl, 500 mM NaCl, 1 mM AEBSF, 2 mM TCEP, 5 mM Imidazole, 0.1% Tween 20, pH 7.5) and lysed by sonication on ice. The soluble fraction was then loaded directly onto an IMAC column (5 mL HisTrap HP) pre-equilibrated with Lysis Buffer and the protein eluted with IMAC Buffer B (40 mM TRIS-HCl, 500 mM NaCl, 1 mM AEBSF, 2 mM TCEP, 300 mM Imidazole, 0.1% Tween 20, pH 7.5). Fractions containing the desired protein were pooled and buffer exchanged by dialysis (MWCO 8,000-10,000 Da) against anion exchange (AEX) Buffer A (20 mM TRIS-HCl, 30 mM NaCl, 1 mM EDTA, 4 mM DTT, pH 8.0).

The protein was then loaded onto a YMC-BioPro ion exchange column (15 x 120, 7.4 mL) pre-equilibrated with AEX Buffer A and eluted over 30 CV with a gradient of 0-50% AEX Buffer B (20 mM TRIS-HCl, 1M NaCl, 1 mM EDTA, 4 mM DTT, pH 8.0).

Fractions were analyzed by SDS-PAGE and those containing the desired protein were pooled and then further purified by SEC (HighLoad Superdex 75 column) using a running buffer of 10 mM TRIS-HCl, 100 mM NaCl, 4 mM DTT, pH 8. SEC fractions were analyzed by SDS-PAGE and the pure fractions pooled and concentrated (Vivaspin column, MWCO 12KDa) to 5.3 mg / mL as measured by UV A280nm.

Crystals of USP7 in complex with 46 were grown by hanging drop vapour diffusion. USP7 (14.2 mg/ml in 10 mM TRIS-HCl, 100 mM NaCl, 4mM TCEP, pH 8.0) was pre-incubated with an 8.9-fold molar excess of 46 (150 mM in DMSO) for 2 h. 0.7 µl of the protein solution was then mixed with 0.7 µl of reservoir solution containing 100 mM TRIS-HCl (pH 7.75), 200 mM Li$_2$SO$_4$, 25% (w/v) PEG4000 and equilibrated at 20°C over 0.4 mL of reservoir solution. Crystals appeared within 4 days.

Diffraction data at 2.2 Å resolution for a USP7/46 crystal was collected at the ESRF synchrotron radiation source, id30a1, Grenoble. The structure was solved via molecular replacement using the PDB structure 5N9R as a template. Iterative manual modelling in Coot and refinement using REFMAC5 resulted in the final model. 97.5% of backbone torsions for the final model are within the Ramachandran favoured regions, with 2.5% in the allowed regions. The crystallography data collection and refinement statistics are provided in Supplementary Table 1 below.

8. In vitro ADME & physicochemical methods:

Kinetic Solubility:
Test compounds (5 μL; 10 mM DMSO stock) were added to 245 μL of PBS buffer pH 7.4 (Dulbecco A) in a Millipore MultiScreen® Solubility Filter plate and mixed at 300 rpm at rt on a plate shaker for 90 min. Meanwhile 5-points calibration curves for each compound were established in a mixture of acetonitrile/PBS buffer (top concentration 200 μM). After filtration and matrix match, the calibration and assay plates were analyzed on a Biotek Synergy 4 plate reader (240-400 nm). Final concentration of the test compound in the filtrate was calculated using the slope of the calibration curve. Two markers were used as controls: hydrocortisone (high solubility KSol >180 μM) and reserpine (low solubility KSol < 25 μM).

**Caco-2 permeability:**

Caco-2 permeability measurements were performed at Cyprotex Ltd. Caco-2 cells obtained from the ATCC are used between passage numbers 40-60. Cells are seeded on to Millipore Multiscreen Caco-2 plates at 1 x 10^5 cells/cm^2. They are cultured for 20 days in DMEM and media is changed every two or three days. On day 20 the permeability study is performed.

Hanks Balanced Salt Solution (HBSS) pH 7.4 buffer with 25 mM HEPES and 4.45 mM glucose at 37 °C is used as the medium in the permeability studies. Incubations are carried out in an atmosphere of 5% CO_2 with a relative humidity of 95% at 37 °C.

On day 20, the monolayers are prepared by rinsing both basolateral and apical surfaces twice with HBSS at 37 °C. Cells are then incubated with HBSS in both apical and basolateral compartments for 40 min to stabilise physiological parameters.

HBSS is then removed from the apical compartment and replaced with test compound dosing solutions. The solutions are made by diluting 10 mM test compound in DMSO with HBSS to give a final test compound concentration of 10 μM (final DMSO concentration 1%). The fluorescent integrity marker Lucifer yellow is also included in the dosing solution. Analytical standards are made from dosing solutions. The apical compartment inserts are then placed into ‘companion’ plates containing fresh HBSS. For basolateral to apical (B-A) permeability determination the experiment is initiated by replacing buffer in the inserts then placing them in companion plates containing dosing solutions. At 120 min, the companion plate is removed and apical and basolateral samples diluted for analysis by LC-MS/MS. Test compound permeability is assessed in duplicate. On each plate compounds of known permeability characteristics are run as controls.

Test and control compounds are quantified by LC-MS/MS cassette analysis using a 5-point calibration with appropriate dilution of the samples. Cyprotex generic analytical conditions are used. The starting concentration (C_0) is determined from the dosing solution and experimental recovery calculated from C_0 and both apical and basolateral compartment concentrations.

The integrity of the monolayers throughout the experiment is checked by monitoring Lucifer yellow permeation using fluorimetric analysis. Lucifer yellow permeation is low if monolayers have not been damaged. If a Lucifer yellow P_app value is above QC limits in one individual test compound well, then an n=1 result is reported. If Lucifer yellow P_app values are above QC limits in both replicate wells for a test compound, the compound is re-tested. If on repeat, high Lucifer yellow permeation is observed in both wells then toxicity or inherent fluorescence of the test compound is assumed. No further experiments are performed in this instance.

**Data Analysis:**

The permeability coefficient for each compound (P_app) is calculated from the following equation:

\[
P_{app} = \frac{\frac{dQ}{dt}}{C_0 \times A}
\]

Where \(\frac{dQ}{dt}\) is the rate of permeation of the drug across the cells, \(C_0\) is the donor compartment concentration at time zero and \(A\) is the area of the cell monolayer. \(C_0\) is obtained from analysis of dosing solution at the start of the experiment.

An efflux ratio (ER) is derived as follows:

\[
ER = \frac{P_{app}(B\rightarrow A)}{P_{app}(A\rightarrow B)}
\]

An efflux ratio greater than two shows efflux from the Caco-2 cells, which indicates that the compound may have potential absorption problems *in vivo*.

The apparent permeability (P_app(A→B)) values of test compounds are compared to those of control compounds, atenolol and propranolol, which have human absorption of approximately 50 and 90% respectively. Talinolol (a known P-gp substrate) is also included as a control compound to assess whether functional P-gp is present in the Caco-2 cell monolayer.

**LogD**: 23
Test compounds (8 μL; 10 mM DMSO stock) was added to 392 μL of PBS buffer pH 7.4 (Dulbecco A pre-saturated with octanol) and 400 μL of octanol (pre-saturated with PBS buffer). The plate was shaken at rt for 4 h. The layers were allowed to separate before being analyzed by HPLC.

Samples were analyzed on an Agilent 1260 HPLC fitted with a Phenomenex Kinetex XB-C18 100Å 2.6 μm 2.1x50 mm column. Mobile phases were water and acetonitrile containing 0.1% formic acid as modifier. The relative drug concentration in each phase was determined by the peak area measurement from LC-UV analysis, UV detection at 254 nm and 210 nm.

Log D<sub>7.4</sub> is calculated as follows:

\[
\text{LogD} = \log \left( \frac{\text{peak area of compound in octanol} \times \text{injection volume of buffer phase}}{\text{peak area of compound in buffer} \times \text{injection volume of octanol phase}} \right)
\]

Three markers were used as controls: caffeine (LogD<sub>7.4</sub> ~ 0), furosemide (LogD<sub>7.4</sub> < -0.5) and reserpine (LogD<sub>7.4</sub> > 3).

Microsomal stability:

Test compounds (final concentration = 1 μM; final DMSO concentration = 0.1%) were incubated in 0.1 M phosphate buffer pH 7.4 with liver microsomes (human, mouse or rat; 0.5 mg of protein/mL) at 37 °C. Reactions were started by addition of NADPH in 0.1 M phosphate buffer pH 7.4 (final concentration 1 mM). 40 μL aliquots were removed at 2, 5, 10, 15, 20, 30, 40 and 50 min. Reactions were quenched in 80 μL of ice-cold methanol containing internal standard. Samples were subsequently frozen overnight then centrifuged at 3500 rpm for 20 min at 4 °C. The supernatants were removed and transferred into analytical plates and analyzed by LC-MS/MS.

LC-MS/MS method: All samples were analyzed on a Waters Acquity I-Class coupled to a Waters Xevo TQD mass spectrometer. A Waters BEH C18 2.1 x 50 mm 1.7 μm column was used and mobile phases were water and methanol containing 0.1 % formic acid as modifier. Analysis was by multiple reaction monitoring and conditions were optimised for each test compound.

Data analyses: From a plot of ln peak area against time, the gradient of the line is determined. Subsequently, half-life and intrinsic clearance are calculated using the equations below:

Eliminated rate constant (k) = (- gradient)

Half-life (t<sub>1/2</sub>) (min) = \( \frac{0.693}{k} \)

Intrinsic Clearance (CL<sub>int</sub>) (μL/min/mg protein) = \( V \times \frac{0.693}{t_{1/2}} \)

Where V = Incubation volume (μL)/mg of protein

Four markers were used as controls for each assay:

9. Pharmacokinetic Profiling of Compounds 46 & 47:

Pharmacokinetics of compounds 46 and 47 were evaluated in healthy male CD-1 mice following a single oral, intravenous or intraperitoneal administration. Dosing solutions for intravenous administration were prepared using DMSO: 20% 2-hydroxypropyl β cyclodextrin (2:98) and administered at a dose level of 1 mg/kg. Dosing solutions for oral administration were prepared using 0.5 % methylcellulose and administered at a dose level of 30 mg/kg. Dosing solutions for intraperitoneal administration were prepared using saline and administered at a dose level of 10 mg/kg. Blood samples
were collected up to 24 h post-dose. In-vivo experiments were carried out at Axis BioServices and pharmacokinetic parameters were measured from blood by XenoGesis Ltd.

A total of 27 male CD-1 mice aged 5-8 weeks, weighing approximately 30-35g were used for the study (animals were bred in-house at Axis BioServices). Mice were housed in IVC cages (5 per cage) with individual mice identified by tail mark. The holding room was maintained under standard conditions: 20-24 °C, 40-70 % humidity and a 12 h light/dark cycle. Animals were fed a standard certified commercial laboratory rodent diet except for overnight fasting immediately prior to dosing; animals were allowed access to food 2 hours after test compound administration. Animals were allowed free access to water at all times during the study.

Dosing solutions were freshly prepared as follows:

For IV dosing solutions:
1.0 mg compound \(46\) was weighed and mixed with DMSO \((40 \mu L)\). 1960 \(\mu L\) of 20% 2-hydroxypropyl β cyclodextrin was added to give a final concentration of 0.5 mg/mL.

1.3 mg compound \(47\) was weighed and mixed with DMSO \((52 \mu L)\). 2548 \(\mu L\) of 20% 2-hydroxypropyl β cyclodextrin was added to give a final concentration of 0.5 mg/mL.

For PO dosing solutions:
12.2 mg compound \(46\) was weighed and mixed with 1mL 0.5% methylcelluose with a pestle and mortar. A further 1.03 mL 0.5% methylcellulose was used to completely wash any compound into the tube, giving a final concentration of 6 mg/mL.

15.2 mg compound \(47\) was weighed and mixed with 1mL 0.5% methylcelluose with a pestle and mortar. A further 1.533 mL 0.5% methylcellulose was used to completely wash any compound into the tube, giving a final concentration of 6 mg/mL.

For IP dosing solutions:
4.5 mg compound \(46\) was weighed and mixed with 1mL sterile saline with a pestle and mortar. A further 3.5 mL saline was added to completely wash any compound into the tube, giving a final concentration of 1 mg/mL.

3.8 mg compound \(47\) was weighed and mixed with 1mL sterile saline with a pestle and mortar. A further 2.8 mL saline was added to completely wash any compound into the tube, giving a final concentration of 1 mg/mL.

The dosing volumes were 2 mL/kg for IV dosing, 5 mL/kg for PO dosing and 10 mL/kg for IP dosing with individual dose calculated from the bodyweight recorded on the day of dosing. At the required time points 100 uL whole blood was removed from the lateral vein into tubes coated with K₂-EDTA. Blood samples were diluted 1:1 with ultrapure water and stored at -80°C before being transported to XenoGesis Ltd on dry ice for bioanalysis. The time points for blood sampling were 5min, 15min, 30min, 1h, 2h, 4h, 8h and 24h for the IV and IP routes. They were 15min, 30min, 1h, 2h, 4h, 6h, 8h and 24h for the PO route. PK parameters were calculated using Phoenix WinNonlin software.
