PURPOSE. To provide a comprehensive and current review on the available experimental animal models of retinal vein occlusion (RVO) and to identify their strengths and limitations with the purpose of helping researchers to plan preclinical studies on RVO.

METHODS. A systematic review of the literature on experimental animal models of RVO was undertaken. Medline, SCOPUS, and Web of Science databases were searched. Studies published between January 1, 1965, and March 31, 2017, and that met the inclusion criteria were reviewed. The data extracted included animal species used, methods of inducing RVO, the risk of complications and having a poorer prognosis than non-ischemic RVO (iRVO) is the most severe form, associated with higher structural damage result of the disease.10,25–59 Furthermore, each of these treatments carries a risk to patients, such as destruction of the retina following laser photocoagulation, endophthalmitis following intravitreal injections, and cataract and glaucoma as a result of steroid administration. Treatments for macular edema that are a result of RVO have been predominantly investigated for the nonischemic form, with most randomized clinical trials excluding or including only few with the iRVO.35,39,40,45,47,52–55,60 In trials in which they have been included, only approximately 50% or less of patients with iRVO show a meaningful improvement in visual acuity following these therapies,34,36–38,41,43, with often poor final visual acuity (≤ 20/100) despite treatment.10,34,36–38,41,43,51,57

Further research is still needed to improve current understanding of the pathogenesis of RVO as well as to identify more clinically effective and cost-effective therapeutic options. This is especially true for patients with iRVO.

Experimental animal models often can be useful to study disease mechanisms and to test the efficacy and potential...
toxicity of new treatments. Such animal approaches have been successful in ophthalmic research, allowing advancement in our understanding of pathogenesis and development of improved novel therapies.61–66 Experimental animal models of RVO also are available, which variously develop functional and structural features resembling those present in people with this disorder. Herein, we aim at providing a comprehensive up-to-date review on experimental animal models of RVO including species, methods of vessel occlusion, their clinicohistopathologic features, and the limits of their translational value. Taken together, this focused and in-depth review ought to help researchers design future studies and appreciate the strengths and weaknesses of the animal models they use.

**Methods**

A systematic review of the literature was conducted, and data sources were Medline, SCOPUS, and Web of Science databases. Keywords including “retinal vein occlusion,” “retinal vein thrombosis,” and “retinal vein obstruction” were combined with “experimental models” or “animal models.” The search covered published articles from January 1, 1965, to March 31, 2017, and was filtered to include articles in English only. The included articles of studies describing methods of creating animal models of RVO and their findings were analyzed, and data contained in these articles were used to inform species-specific model systems, the range of methods for inducing vein occlusion, pathologic and clinical features developed in these models, and strengths and limitations of available models. The information extracted was used to populate Tables 1 through 8 of this review. In addition, their clinical value and potential translational implications for the management of patients with this disorder was considered. Changes on levels of cytokines/chemokines/growth factors and other biochemical and molecular events occurring as a result of the induction or RVO in these models, as well as effects of treatments tested in these models, are not summarized herein.

**Results**

**Studies Included**

After removal of duplicates, a total of 320 titles were identified and their abstracts obtained and evaluated for potential inclusion in the review. Of the 320 abstracts, 193 were found to relate to studies outside the scope of this review and, therefore, were excluded. Full articles of the remaining 128 studies were obtained, found to be directly related to the topic of this review, and used to extract pertinent data.

**Species**

Several animal species have been used to study RVO, including rodents,67–100 rabbits,101–114 cats,115–124 dogs,125–127 pigs,128–156 and nonhuman primates82,111,129,157–196 (Tables 1, 2). Each of these species has its own size and anatomic advantages, but also ethical challenges and cost implications; these have been summarized in Table 3. Although the retina and retinal vessels of these animals share many anatomic features with humans, differences still exist and are more pronounced in some species (Table 4). None of the animal models, with the exception of the nonhuman primate, have an anatomic macula or fovea centralis.197 Pigs,198–202 cats,201,203 and dogs198,204 have a central retinal area with high density of ganglion cells and cone photoreceptors known as area centralis, which would correspond to the fovea centralis in humans but is less specialized and cannot be identified by gross fundus examina-

Bolded values represent models that addressed macular edema or ischemic features. Ischemia defined by one or more of the following criteria: development of neovascularization, extensive areas of retinal capillary nonperfusion, or areas capillary nonperfusion associated with atrophy/cell loss of the inner retinal layers (≥ outer retinal layers). MO, macular edema; n, number of articles.
Several techniques have been used to induce an RVO in experimental animals. These have been summarized, including their advantages and disadvantages, in Table 5. In most cases, experimental RVO has been induced by traumatizing one or more retinal veins using laser photocoagulation,67–75,80–92,96–97,101,104–111,115–118,125–127,129–147,156–167,174,176–194,216 photodynamic coagulation,95–97,112,148–149 photodynamic catarization,75,120–124,150–152 or intravitreal injection of PD032590,114

Branch Retinal Vein Occlusion. Experimentally, BRVO has been produced by using laser photocoagulation,70,80,89–96,97,100,105,127,132,142,146,156,176,178,181,216 photodynamic coagulation,95–97,112,148–149 photodynamic catarization,75,120–124,150–152 or intravitreal injection of PD032590,114

Laser Photocoagulation. In this method, laser irradiation is performed on selected retinal veins to produce BRVO.70,80,89–96,97,100,105,127,132,142,146,156,176,178,181,216 Classically, burns are placed approximately 0.5 to 2.0 disc areas from the optic disc, avoiding damage to the retinal arteries.69–72,117,186,217 Laser photocoagulation is typically done on the slit-lamp using a contact lens.69–72,117,186,217 Several techniques have combined laser photocoagulation with vitrectomy.147,170–178

Different types of laser and wavelengths have been used, commonly 514-nm Argon, and their parameters varied depending on the type of laser used, type of animal, and use or not of adjuvants (Table 6). Photosensitizers, such as Rose Bengal,67–70,73,81,89,96,99–101,104,106,107,109,110,126,127,132,134,135,137,139,141,143,146,147,217 erythrosin B,74 sodium fluorescein,71,83,85,86,88,97,99,100,104,106,117,126,132,134,135,137,139,141,143,146,147,217 chloroaluminium sulfonated phthalocyanine,105 PAD-S31,186 and mono-L-aspartyl chlorin e6 (NPe6)62 have been commonly used with the laser photocoagulation to minimize the amount of the laser energy required to produce the RVO. Rose Bengal has been the most commonly used photosensitizer,147,170–178 whereby the dye is infused systemically (10–50 mg/kg) and the retinal vessels are exposed to highly focused laser irradiation.67–70,73,81,89,96,99,101,104,106,107,109,110,126,127,132,134,135,137,139,141,143,146,147,217 Combination of intravitreal injec-
tion of thrombin (50 units) and laser photocoagulation has also been reported. Endophotocoagulation has also been used to achieve a vein occlusion; for this technique, an endolaser probe is inserted into the eye through a sclerostomy (without removing the vitreous) and retinal veins are then photocoagulated until evidence of occlusion is seen.146,147

**Photodynamic Therapy.** Photodynamic coagulation is another method that has been used to induce BRVO. 93–95,112,119,148,149 This method involves light illumination using a slit-lamp and a contact lens, or an endo illuminator in combination with vitrectomy aiming at selected retinal vein or veins, with care not to damage retinal arteries, for a duration ranging between 6 and 20 minutes until evidence of venous occlusion is observed.93–95,112,119,148,149 Photosensitizers, such as Rose Bengal,93–95,112,119,148,149 sodium fluorescein,119 and NPe6,82 have been used in different doses depending on the species used to facilitate thrombus formation.

**Diathermic Cauterization.** An alternative way to produce experimental BRVO is by using diathermy, which has been undertaken via a pars plana sclerotomy.75,120–124,150–152 In cats, BRVO has been induced with indirect ophthalmoscopy and 20-gauge bipolar diathermy that is applied to the targeted vein/veins for 5 seconds.120–124 In pigs, a technique has been described that produces a BRVO following a temporal canthotomy, conjunctival incision, and performance of three sclerotomies at 10, 2, and 5 o’clock, 2 mm posterior to the corneal limbus.150–153 In this method, a light source and a blunt bipolar diathermy probe are inserted into the vitreous and one or two major retinal veins are coagulated approximately 1 disc diameter away from the optic disc for 5 to 7 seconds after 5 seconds of compression and under direct view.

through an operating microscope and with the aid of a fundus contact lens. This procedure does not involve vitrectomy.

**Intravitreal Injection of Substances.** PD0325901 (N-[2,3-dihydroxy-propoxy]-3,4-difluoro-2-[fluoro-4-iodo-phenylamino]-benzamide) is a mitogen-activated protein kinase inhibitor that has been used in clinical trials for the treatment of solid tumors and has been found to be associated with development of BRVO. Based on this, one study established a rabbit model of BRVO by a single intravitreal injection of PD0325901 (0.5 or 1.0 mg per eye) using a 27-gauge needle inserted approximately 3 mm posterior to the limbus at the superior temporal quadrant and advanced until into the vitreous cavity.

**Central Retinal Vein Occlusion.** CRVO has been produced by laser photocoagulation,167–170,172,195 diathermic cauterization,168–172,195 permanent ligation of the central retinal vein,174 transient clamping/ligation of the optic nerve,76–79 or intravitreal injection of thrombin,102,219 NPe6,103 or endothelin-1 (ET-1).113

**Laser Photocoagulation.** In this method, all major branches are irradiated with laser to produce CRVO 67–75,101,111,157–167,169 classically 0.5 to 2.0 disc areas from the optic disc, avoiding damaging the retinal arteries,69,70,74,80,81,92,97,99,117,186,217 similar to BRVO, laser photocoagulation is typically done on the slit-lamp using a contact lens.68–72,74,81–83,85,86,88,89,102,103,117,126,152,154,155,157,159,141,186,187,192–194,196 with or without vitrectomy.147,176–178 Different types of laser, wavelengths, and photosensitizers have been used.57–71,73,74,80,83,85,86,88,89,96,97,99,101,104–107,109,110,126,127,132,154,155,157,159,141–143,146,147,166,175,186,187,190–194,217,218,220 In one study, a through-and-through suture was placed in the cornea, in addition to the laser photocoagulation in nonhuman primate models, to create an aqueous leak and subsequent hypotony to produce iris neovascularization.166

**Diathermic Cauterization.** Diathermic cauterization of the central retinal vein has been achieved through a lateral orbitotomy approach in nonhuman primates to produce CRVO.168–170,172,195 In this method, diathermy is applied at the central retinal vein on the inferiomedial aspect of the optic nerve as it exits the optic nerve sheath, avoiding injury to the ciliary vessels.166–170,172,195

**Mechanical Ligation.**

- Permanent ligation of central retinal vein: Mechanical ligation of the central retinal vein was used in nonhuman primates to produce CRVO in one study.174 Through a lateral orbital approach and using the operating microscope to aid visualization and achieve adequate magnification, the central retinal vein was identified and ligated using an 8-0 silk suture. Two approaches were then used to achieve a CRVO: (1) a small incision was made proximal to the suture and neovane was introduced through a cannula into the central retinal vein where it solidified, or (2) the central retinal vein was cut after ligation.174
- Transient ligation or clamping of the optic nerve: Transient ligation/clamping (60–120 minutes) of the optic nerve using a lateral orbital approach has been used also to produce CRVO in rats and in pigs.76–79 This method, however, included the ciliary vessels and the central retinal artery and, thus, not reproducing an isolated CRVO.

**Intravitreal Injection of Substances.**

- Thrombin: A different CRVO model, the Hirosaki model, was developed in rabbits as described in one study.102 Based on the premise that the extrinsic coagulation mechanism can be triggered by thromboplastin in the perivenous connective tissues, CRVO was successfully created through the intravitreal injection of thrombin over the wall of the rabbit’s retinal veins (thrombin solution 0.01 mL [5 units]) under direct vision using a 27-gauge needle. A Goldmann contact lens and operational microscope were used to view the fundus.102
- NPe6: Another animal model of CRVO, also in rabbits, described in one study, involved an intravitreal injection of a hydrophilic photosensitizer, mono-L-aspartyl chlorin e6 (NPe6) (50 and 100 µg). In this model, there was no direct exposure to a light source, instead the animals were naturally exposed to the daily light-dark cycle. The injection was performed approximately 2 to 3 mm posterior to the limbus using a 30-gauge needle and a 1-ml syringe.103 In this particular model, CRVO, central retinal artery occlusion, and various degrees of vitreous hemorrhage developed after 1 week following injection.
- ET-1: ET-1 is a peptide with vasoconstrictive properties normally produced by vascular endothelial cells.113 Intravitreal injection of 1000 pmol of ET-1 solution over the disc, as observed by opthalmoscope, using a 29-gauge needle and a 1-ml syringe was used to induce CRVO in rabbits in one study.113 In this model, the occlusion lasted only 50 to 70 minutes.113

**Clinical and Histopathologic Features of RVO Models**

Clinical and/or histopathologic features observed in animal models of BRVO and CRVO were described in 89 and 38 articles, respectively, identified in our search. Macular edema has been addressed in only 4 of 21 studies on nonhuman primate models of BRVO, all laser-induced,180,186,190,193 and in only 2 of 21 studies in nonhuman primate models of CRVO,

| Laser photocoagulation ± photosensitive dye | • Can be used to produce both CRVO and BRVO  
• Easy to undertake  
• Successful in 89%-100% of cases  
• Many studies supporting this technique | • Potential phototoxicity with photosensitizers and sun/light exposure  
• Inner retina damage at the site of the laser treatment  
• May rupture retinal vessels and cause vitreous hemorrhage  
| Photodynamic therapy + photosensitive dye | • Produces BRVO  
• Successful in 50%-100% of cases | • Potential phototoxicity with photosensitizers and sun/light exposure  
• Inner/outer retinal damage at the site of the light application  
• Exudative retinal detachment  
• Retinal necrosis  
• Requires specialized equipment | 93-95, 112, 119, 148, 149 |
| Diathermic cauterization | • Produces CRVO and BRVO  
• Successful in 90%-100% of cases | • Invasive  
• Requires access to surgical facilities to produce CRVO | 120-124, 150-153, 168-170, 172, 173, 195 |
| Permanent ligation of the central retinal vein | • Produces CRVO  
• Successful in 100% of cases | • Invasive  
• Requires access to surgical facilities to produce CRVO  
• May affect ciliary vessels and central retinal artery  
• Only 1 reported study | 174 |
| Transient ligation/clamping of optic nerve | • Produces CRVO  
• Successful in 100% of cases | • Invasive  
• Requires access to surgical facilities to produce CRVO  
• Affects ciliary vessels and central retinal artery | 76-79, 128 |
| Intravitreal thrombin injection | • Produces CRVO  
• No mechanical vascular damage | • Successful in only 43% of cases  
• Only 1 reported study | 102 |
| Intravitreal ET-1 injection | • Produces BRVO  
• Successful in 100% of cases  
• No mechanical vascular damage | • Only 1 reported study  
• Transient occlusion (50-70 minutes)  
• Affects both retinal arteries and veins | 115 |
| Intravitreal NPe6 injection | • Produces BRVO  
• Successful in 100% of cases  
• No mechanical vascular damage | • Only 1 reported study  
• May produce features unrelated to RVO | 105 |
| Intravitreal PD0325901 injection | • Produces BRVO  
• Successful in 100% of cases  
• No mechanical vascular damage | • Only 1 reported study  
• May produce features unrelated to RVO  
• Takes 1 week to produce RVO | 114 |

BRVO, branch retinal vein occlusion; CRVO, central retinal vein occlusion; RVO, retinal vein occlusion; ET-1, endothelin-1; NPe6, mono-L-aspartyl chlorin e6.

Both diathermy-induced,170,195 ischemia, defined by development of neovascular complications, extensive areas of capillary nonperfusion (capillary dropout), or both, or capillary nonperfusion associated with atrophy/cell loss of the inner retinal layers, has been reported in 28 of 89 studies in laser-induced BRVO models of rodents (n = 8),80,83,85,89,90,92,96,97 pigs (n = 6),130-134,154 and nonhuman primates (n = 13),175,176,178-181,184,187-190,192,193,199; PD0325901-induced BRVO models of rabbits (n = 1),114 and in 16 of 38 studies in laser-induced CRVO models in rodents (n = 4),67-69,74 rabbits (n = 1),101 and nonhuman primates (n = 9),157-160,162-166 in permanent ligation of central retinal vein CRVO models in nonhuman primates (n = 1),174 and in thrombin-induced CRVO models in rabbits (n = 1).102

The features described in this section, unless otherwise specified, do not refer to the changes observed at the site of the occlusion and caused by the procedure used to create the RVO itself, but rather those result of the vein occlusion.

All models showed early features classically observed in human BRVO and CRVO, including cessation of blood flow and venous dilation, engorgement, and tortuosity distal to the

CASPc, chloraluminium sulfonated phthalocyanine; IP, intraperitoneal; IV, intravenous; N/A, no data available.
occlusion site. Moreover, all models, except the ET-1-induced CRVO, showed retinal hemorrhages and various degrees of retinal edema, which were commonly observed within the first 48 hours of RVO induction. 70,74,80,83–85,89,90,93–95,108,109,112–115,117,151,154,155,157,159,161,165,167,170,178,180,187,189,191,192,195,216,221 peaked at day 4 and resolved 7 to 28 days following occlusion. 70,74,75,89,96,97,102,108,129,156,169,170,172,192,193,221 various degrees of exudative retinal detachment developed in many eyes of laser-induced and diathermy-induced CRVO. 67,74,80,85,89,96,97,105,115,121,124,126,132,186 and laser-induced CRVO eyes. 67,70,174 Bullous retinal detachment also was observed in many models that resolved spontaneously during follow-up. 67,70,74,85,88 Changes in the thickness of the overall retina and individual retinal layers as a result of the edema (thickening) or ischemia (thinning) were evaluated mainly by histopathology. 70,74,76,89,91,92,94,95,114,121,129,131–133,151,154,169,170,177,180,189,199,202, in five studies, optical coherence tomography (OCT) was used also for this purpose. 75,80,90,91,100 Both CRVO and BRVO models showed significant increase in the thickness of the inner retinal layers 1 to 4 days postinduction, followed by gradual reduction over time, with follow-up periods ranging between 7 and 28 days. In many models, retinal thickness was reduced during the follow-up to values below those detected at baseline (atrophic thinning); this was observed at 7 to 14 days from RVO induction. 75,80,90,91,100

### Branch Retinal Vein Occlusion. Macular Edema

Macular edema in the nonhuman primate models was observed as early as 1 to 6 hours following venous occlusion 70,80,193 and became prominent at 7 to 9 days postocclusion. 70,193 It was found in up to 100% of treated eyes in one of the four studies on nonhuman primate models that described macular edema in induced BRVO (see above). 180 Both intracellular neural and extracellular edema were reported. 180,193,194 The edema was mainly observed in the nerve fiber layer and outer plexiform layer. 190,193 Adjacent to the extracellular edema often appeared shrunk or compressed. 190,193 In addition, macular edema was often associated with photoreceptor cell loss, which persisted after resolution of macular edema. 180,196,193 Spontaneous resolution of macular edema occurred in all occluded eyes between 14 days and 2 years after laser photocoagulation clinically. 180,196,193 In one study, histopathologic examination of six eyes at 48 months showed cystic spaces in the outer plexiform layer in four of six eyes. 180

### Retinal Capillary Nonperfusion and Reperfusion

Various degrees of capillary nonperfusion in laser-induced, diathermy-induced, and PD325901-induced models of BRVO were reported. 90,107,120–122,124–129,132,151,154,179,187,189,190,192,195,222 Areas of capillary nonperfusion were observed as early as 5 days following venous occlusion 85,89 and found to progress with time. 70,179,192 Extensive or severe areas of capillary nonperfusion were prominent 1 to 4 weeks following vein occlusion 182,187,192,222 and were observed in up to 75% of eyes. 96,153,221 The areas of capillary nonperfusion persisted during the follow-up, which ranged between 1 and 20 weeks, despite reperfusion. 70,80,85,89,92,96,97,132,153,150,175,179,189,191–193,221,222 Reperfusion in these models was either by recanalization/reopening of the occluded vessels in some or all eyes, 70,80,85,89,90,92,95,95–97,104,105,110,112,115,120,126,129,152,153,157,168,187,192 or development of collateral vessels. 85,89,92,96,104,105,120,121,124,129,133,135,175,179,180,183,187,189,192,221,222 Recanalization was observed in 0% to 100% of eyes of BRVO models 1 to 14 days following induction. 70,80,85,89,92,95,97–99,104,105,110,112,126,129,132,135,186,221 Collateral vessels were observed in 5 to 14 days following establishment of the RVO. 92,129,179,180,192 (Tables 7, 8).

### Neovascular Complications

Posterior segment neovascularization occurred in some laser-induced BRVO models in rodents, 85,89,96 pigs, 132,154,154,221 and nonhuman primates, 175,188,189,192 but not in the other BRVO models. Retinal and/or disc neovascularization was observed in 8.3% of eyes as early as 7 days postocclusion 89 and in 60% to 70% of eyes 14 days following laser induction in rodent models. 89 In laser-induced pig models, retinal and/or disc neovascularization were described in approximately 50% to 93% of eyes 3 to 4 weeks following RVO induction 122,133,221,222 and up to 100% of eyes at 6 weeks. 134,154 In laser-induced nonhuman primate models, 9% of eyes developed retinal neovascularization at 4 weeks. 192 Anterior segment neovascularization was observed in laser-induced nonhuman primate models when three major branches were targeted. 176,178,181,184 In this model, up to 100% of eyes developed iris neovascularization within the first 6 days of occlusion 176,178,181,184 and 17% to 20% developed neovascular glaucoma within 25 days of follow-up. 176,178 There was no spontaneous regression during follow-up of 28 to 84 days. 86,90

### Vascular Endothelial and Pericyte Cell Loss

Damage and loss of the vascular endothelial cells and pericytes was detected by histopathologic examination in experimental animal models of BRVO. 80,107,120,187,190,193 which resulted in graft acellular vessels with glial invasion. 176,187,193 observed as early as 1 to 48 hours postocclusion. 70,120,190,193 Endothelial cell apoptosis was detected as early as 1 day postocclusion. 190 Reduced cell loss was observed 3 days following occlusion and significantly worsened at 7 days with 40% pericyte cell loss detected.90

### Retinal Atrophy

Atrophy (thinning/loss) of the inner retinal layers 70,74,80,89,91,92,94,95,121,127,151,153,151,154,179,179,187,189,190,192,195,222 and replacement with glia 151,152 has been reported. The loss of the inner retinal layers was first observed 3 days postocclusion 80 and was marked at 7 to 28 days of follow-up. 70,74,80,89,91,92,95,132,153,151,190,192 Damage of the outer retinal layers and loss of the photoreceptors was observed distal to the site of the occlusion in some eyes with laser-induced BRVO and ischemia at 3 to 6 weeks postocclusion. 132,153,222 Photoreceptor cell loss was observed in 67% of eyes at 3 months following the occlusion. 80 Damage to the photoreceptors was reported in photodynamic-induced thrombosis in rats within 2 days of the occlusion, which was most likely related to the photodynamic therapy itself rather than the result of ischemia. 112 Unspecified RPE changes were reported 4 weeks to 3 months following occlusion in laser-induced BRVO nonhuman primate models. 152,190,192

### Functional Changes

When conducted, ERG studies showed reduction of the “a” and “b” wave amplitudes of both scotopic and photopic ERG at 1, 2, 3, 4, 6, and 7 days following laser-induced BRVO in rat models 80,100. In multifocal ERG, a significant decrease in the P1 and N1 amplitudes and prolonged implicit times in the affected retina were observed 4 weeks following thrombus formation in diathermy-induced BRVO in pig models. 151,152

### Other Features

Other features also were observed in some eyes with experimental animal BRVO, such as cotton wool spots, detected at 3 days to 6 weeks in laser-induced nonhuman primate models. 80,192 venous sheathing between 7 days and 3 months, 125,127,129,152,152 microaneurysms 1 to 8 months, 20,125 and reduction of preretinal oxygen saturation measured at different time points between 60 minutes and 3 weeks following occlusion. 130,121,124,131,150,222

### Central Retinal Vein Occlusion. Macular Edema

Macular edema was observed as early as 48 hours following venous thrombosis in 14% to 66% of CRVO nonhuman primate models induced by diathermy. 170,195 This had resolved spontaneously in all eyes 14 days following induction. 170,195 (Tables 7, 8).

### Capillary Nonperfusion and Reperfusion

Various degrees of capillary nonperfusion were reported in laser-induced,

</table>
permanent ligation of the central retinal vein, and thrombin-induced CRVO models. In one of these studies, it was found to become extensive 2 to 4 weeks following the induction of CRVO and progressed to involve up to 75% of the retinal area 7 weeks postinduction of RVO by laser photocoagulation in 67% of eyes. In thrombin-induced CRVO in rabbits, extensive areas of retinal capillary non-perfusion were observed at 3 months following the occlusion.

Recanalization or reopening of the occluded vessels was reported in many studies of laser-induced CRVO. This was observed 1 to 21 days postocclusion in 6% to 80% of eyes. Collateral vessels were also reported in some eyes at 2 weeks to 2 months of follow-up following laser-induced and thrombin-induced CRVO.

Neovascular Complications. Neovascular complications were observed in laser-induced and thrombin-induced CRVO. In nonhuman primate models of RVO, preterinal neovascularization was reported in 1 to 3 weeks following laser photocoagulation in 17% to 90% of rats, with no spontaneous regression described. In nonhuman primate models, however, posterior segment neovascularization was detected in one study, in which disc neovascularization was detected in 17% of eyes due to 25 to 26 days postocclusion that resolved spontaneously at day 87, but not in other studies with follow-up periods ranging between 1 and 24 weeks.

Thrombin-induced CRVO in rabbits showed retinal neovascularization in 60% of eyes at 3 months following injection. Spontaneous regression of neovascularization in this model was not reported. Iris neovascularization was observed only in laser-induced nonhuman primate models.

Vascular Endothelial and Pericyte Cell Loss. Vascular endothelial and pericyte cell loss has not been described in experimental models of CRVO. Retinal Atrophy. Aretinal thinning in rats was observed in 1 to 6 weeks following laser photocoagulation, and retinal layers and cell loss was reported 7 to 21 days in rodents and rabbit models following laser photocoagulation.

Other Features. Disc hyperemia was observed within 48 hours in up to 100% of diathermy-induced CRVO in nonhuman primate models, which was secondary to the procedure rather than to the CRVO.

Strengths and Limitations of Available Animal Models

Although none of the animal RVO models described above develop all features occurring in human RVO, almost all models demonstrate the early characteristics of this disease, including retinal hemorrhages and edema, which may make them adequate models to study the acute phase of both BRVO and CRVO. Only a few models, however, developed macular edema (i.e., laser photocoagulation in BRVO nonhuman primate models and diathermy in CRVO nonhuman primate models) in up to 100% of eyes, which makes the study of this particular feature difficult.

Most animal models of RVO demonstrated spontaneous reperfusion and/or vascular remodeling, which seemed to occur more rapidly and effectively than in humans with RVO. As a result, persistent ischemic features failed to develop in most models, and iris neovascularization was not observed, except in laser-induced nonhuman primate models, which was secondary to the procedure rather than to the CRVO. The lack of ischemic features (i.e., extensive areas of retinal nonperfusion and/or neovascularization) being observed in other models may be attributed to the inadequate follow-up time in some of the studies or may be due to other factors such as the nature of the occlusion induced by the various techniques, including duration of the occlusion, and the timing and characteristics of the reperfusion that followed. There are still limitations of the models available that reproduce best retinal ischemia and neovascularization. For example, the laser-induced rodent model of BRVO and CRVO may pose difficulties due to the small size of the eye (Fig.), the large crystalline lens, and the thin and delicate sclera, which may make the undertaking of functional and imaging studies as well as therapeutic interventions challenging. The lack of a macula in many nonprimate models makes it impossible to study macular edema and, although as stated above the occlusion can be produced with high success (92%–100%, see Table 8), neovascularization occurs variably (60%–70% and 17%–90% in models of BRVO and CRVO, respectively). The laser-induced pig model of BRVO appears to be ideal due to anatomical similarities (see Table 4), including the presence of an area centralis, and the high success at achieving vein occlusion (93%–100%) and development of neovascularization (100%) in a relatively short period (6 weeks). Furthermore, the larger size of the eye in this model facilitates functional, structural, and interventional studies. Pigs are larger animals, posing other difficulties (see Tables 3, 5). Nonhuman primate models of laser-induced ischemic CRVO and BRVO best mimic the clinical and histopathologic features observed in humans; however, the use of this species carries major ethical considerations and other inconveniences, such as high cost (see Tables 3, 5) and are not available to most researchers.
Although therapeutic strategies are available for people suffering from RVO, these are limited, and a relatively large proportion of patients still lose sight as a result, especially those with iRVO. Treatment is, at present, delivered only once per treatment period. This will subsequently reduce testing times that develop its features more consistently and in shorter periods of time. This will help to better understand the pathogenic events taking place in RVO. It will also help researchers in the development of new treatment modalities by allowing them to select those that mimic more closely the human disease, that develop its features more consistently and in shorter periods of time. This will subsequently reduce testing times and costs and will improve the planning and design of future, more successful studies as well as the potential for translation to clinical practice.
