Abstract—We present the first use of a circular array for retrodirection covering full 360°. In particular, we discuss the attributes of the circular array when combined with Rotman beam forming. For reference the characteristics of the circular array when performing retrodirective action using local per element conjugation is also demonstrated. Simulated and measurement results at X-band are presented. The retrodirective circular array provides the advantage of 360° coverage when compared to other retrodirectors based on uniform linear arrays, as these typically allow only up to ±40° sector coverage.

Index Terms—Circular array, retrodirective array, phase conjugation.

I. INTRODUCTION

A retrodirective array retransmits the received signal in the direction of the source without prior knowledge of source direction. Thus, they find application in communications [1], target tracking [2], and RCS enhancement [3]. In this paper, we show how a circular array equipped with a Rotman lens can be used for 360° azimuthal retrodirective beam steering. The design of circular arrays by modal analysis technique for beam forming and steering are discussed in [4-8]. The use of beamforming networks using the Rotman lens are described in [9], respectively. In [10] and [11] the use of a Rotman lens in a ULA based retrodirective array was discussed. We also show that by using a Rotman lens feeding a circular array we initiate retro directive application for full 360° coverage. We describe how the mechanism for retrodirective action using a Rotman lens is different from a Rotman lens fed retrodirective uniform linear array (ULA). In addition, for reference, we discuss the self-steering properties of the circular array when the signals arriving at the antenna elements in the circular array are individually and ideally phase conjugated.

Section II describes the principle of operation of the circular array along with a 12 element microstrip patch radiating element implementation. In section III, we discuss direct per-element phase conjugation and mode-pair interconnect methods for circular array retrodirection and present the measured results obtained for a Rotman lens fed circular array for retrodirective operation. Finally conclusions on the work are given.
When many beam ports are simultaneously excited then the output current distribution is the summation over \( K \) for the \( N \) element array. Consequently, the far-field radiation pattern assuming the approximate pattern of dipole \( A(\phi) \) as \( 0.5 \times (1 + \cos(\phi)) \) is given by

\[
E(\phi) = \sum_{J=1}^{N} \left( \sum_{i=1}^{J} B_i e^{i(\beta r_i - \alpha_i)} \right) A(\phi - \alpha_i) e^{i(\beta r_i \cos(\phi - \alpha_i))} \tag{4}
\]

When \( \beta = 2\pi/\lambda, \lambda \) is the wavelength of operation, and \( r \) is the radius of the array \([4, 5]\), \( \alpha_i \) is a general representation of element angular location in a circular array with \( N \) equally spaced elements at \( \alpha_i = \beta \pi/N, \text{ when } J = 1, 2, \ldots, N \). Referring to the circular array center, the relative phase of the \( J \)-th element in this case would be \((2\pi/r) \cos (\phi - \alpha_i) \).

**B. Circular micro-strip patch antenna array**

The radiating element for the demonstration array was chosen for ease of fabrication as a microstrip patch, operating at 9.3 GHz, and constructed on dielectric RO40003C (\( \varepsilon_r = 3.38 \) and loss tangent = 0.0027). The calculated dimensions for the above specifications are patch width = 10.14 mm, length = 7.52 mm, height \( h = 0.51 \) mm, and the substrate \( \varepsilon_r \)-eff = 3.13. The full-wave electromagnetic simulation based \([S_{11}]\) was below -10 dB at 9.5 GHz. A circular array with 12 elements (having an angular separation between neighboring elements = 30°) was designed with the above patch elements. The separation between the elements is 0.5\( \lambda \) and the diameter of the array is approximately 2\( \lambda \), i.e. 60 mm at 9.3 GHz. The circular array was assembled on Styrofoam (see Fig. 1). The isolation between adjacent patches was < 25 dB.

A micro-strip based Rotman lens (RL) designed and fabricated in accordance with the method in [11] (see Fig. 2). The radiating elements are attached to the array ports while the interconnecting lines necessary for retro direction action are attached to complementary beam ports. The measured beam port \([S_{11}]\) are all below -10 dB and the nearest beam port-to-port isolation is better than 15 dB. Maximum lens insertion loss is 18 dB. When the modes of the CA are phase aligned \([4]\), then summed, beam-forming occurs. From Fig. 3 we conclude that using \( \pm 4 \) modes with the RL and CA would yield reasonable results for beam-forming.

**III. RETRODIRECTIVE CIRCULAR ARRAY**

As explained earlier in the introduction a retrodirective array redirects incident signal back in the direction from which it came from. This can be made possible by conjugation of the phase received at each array element when the CA is illuminated with a plane wave whose polarization is matched to the patch array and which is applied at different angles of incidence (AOI). Here the antenna array elements are made to sample the signal incident upon them at the design frequency (i.e. 9.3 GHz). The induced signals at each of the array element circuit ports are conjugated, and are used to re-excite the array in transmit mode. The signals self-beam form to retrace their path back in the angle of arrival (AOA) from the signal source. The resulting simulated far-field radiation patterns under the above ideal phase conjugation voltages applied as excitation for the array in Fig.1 are shown in Fig. 4. These serve as a benchmark for comparing the RL method of retrodirection.

The suggested technique should find application in radars and wireless communications.

ACKNOWLEDGMENT

The authors would like to acknowledge the PhD scholarship support given by the Queen’s University Belfast and to the EPSRC under the grants EP/P000673/1, EP/NO20391/1. The authors would also like to thank Mr. Kieran Rainey for fabrication and testing of the circular patch array.

REFERENCES

IV. CONCLUSIONS

The operation of a twelve element circular array with a Rotman lens for retrodirection is presented. This shows the utility of using a Rotman lens in combination with a circular array for 360° sector coverage by retrodirection.
