Abstract

Background: Staff who provide end-of-life care to children not only have to deal with their own sense of loss, but also that of bereaved families. There is a dearth of knowledge on how they cope with these challenges.

Aim: The aim of this review is to explore the experiences of health care professionals who provide end-of-life care to children in order to inform the development of interventions to support them, thereby improving the quality of paediatric care for both children and their families.

Data sources: Searches included CINAHL, MEDLINE, Web of Science, EMBASE, PsychINFO, and The Cochrane Library in June 2015, with no date restrictions. Additional literature was uncovered from searching reference lists of relevant studies, along with contacting experts in the field of paediatric palliative care.
Design: This was a systematic mixed studies review. Study selection, appraisal and data extraction were conducted by two independent researchers. Integrative thematic analysis was used to synthesise the data.

Results: The 16 qualitative, six quantitative, and eight mixed-method studies identified included healthcare professionals in a range of settings. Key themes identified rewards and challenges of providing end-of-life care to children, the impact on staff’s personal and professional lives, coping strategies, and key approaches to help support staff in their role.

Conclusions: Education focusing on the unique challenges of providing end-of-life care to children and the importance of self-care, along with timely multidisciplinary debriefing are key strategies for improving healthcare staffs’ experiences, and as such the quality of care they provide.

Keywords
Healthcare staff, experience, end-of-life, children, mixed method review

What is already known about the topic?

- One of the leading causes of death among children is chronic conditions requiring end-of-life care
- The death of a young patient has a huge impact on the professional and personal lives of the healthcare professionals involved in their care
- There is a dearth of knowledge on how healthcare professionals cope with the challenges of paediatric palliative care

What this paper adds?
• This review identified staff rewards as well as challenges when providing end-of-life care to children
• A wide range of healthcare staff feared grieving in public
• Finding meaning, closure, and practicing self-care were important strategies for helping staff cope with the death of a young patient

**Implications for practice, theory or policy**

• This review highlights the need for healthcare organisations to support and care for staff who provide end-of-life care to children, through the provision of ongoing paediatric palliative care education and timely multidisciplinary debriefing
• Effective models of multidisciplinary working and co-ordination of services are important for mitigating the stress experienced by healthcare professionals when providing end-of-life care to children
• The experiences of doctors and support staff providing end-of-life care to children are areas requiring further research, along with experiences encountered within the hospice setting

**Introduction**

The death of a child is considered unthinkable in Western culture, with the general belief that children will always outlive their parents.¹ However, over 3,000 babies younger than one, and over 2,000 children and young people aged between one and 19 died in the United Kingdom during 2012. One of the leading causes of death were chronic conditions.² On a global scale, 160,000 cancer diagnoses were made in children under the age of 15, and caused 90,000 deaths every year.³ However,
although palliative care and hospice services are well established in adult medicine, paediatric palliative care is a comparatively young discipline.\textsuperscript{4} 

Although advances have been made in recent years to broaden palliative care to children, the research base and training for paediatric palliative care still falls short in comparison to adult palliative care.\textsuperscript{5} Paediatric care is unique because of the need to have parents/guardians involved in caring procedures and decision making, while also taking due cognisance of the child’s right to have their views and wishes respected according to their level of development and independence.\textsuperscript{6} Paediatric palliative care is defined as ‘the active total care of the child’s body, mind and spirit’.\textsuperscript{7} In common with all forms of palliative care, it focuses on improving ‘the quality of life of patients and their families facing … life-threatening illness’.\textsuperscript{7} 

When a child dies, the effect on the family is overwhelming.\textsuperscript{8} Likewise, for those healthcare professionals who provide end-of-life care to children, the death of a young patient has a huge impact on their professional and personal lives.\textsuperscript{9-11} Mental health risks in relation to professionals who work in stressful situations has been recognised for quite some time.\textsuperscript{12} Professionals who provide palliative care are at high risk for a number of reasons. Prolonged exposure to death may intensify unresolved losses and produce grief responses or underlying depression, which can have a negative impact on personal relationships with friends, partners and family members.\textsuperscript{13}
The extant literature reinforces the proposition that supporting health care professionals in the palliative setting improves patient care.\textsuperscript{14,15} However, while national and international policy and guidance acknowledge the key role of children’s nursing services for providing palliative care, there is little recognition of the impact such care has on the nurses and other healthcare professionals involved.\textsuperscript{16} The main aim of this review was to systematically explore the experiences of health care professionals who provide end-of-life care to children, the impact this has on health care professionals, and how they cope, in order to draw recommendations for interventions to support them, thereby improving the quality of paediatric care for both children and their families.

**Main research questions**

- What are the experiences of healthcare professionals who provide end-of-life care to children?
- How do these experiences impact on the professional and personal lives of healthcare professionals?
- How do healthcare professionals cope with the impact/challenges of providing end-of-life care to children?
- On the basis of the answers to the above questions, what interventions have the potential to support healthcare professionals who provide end-of-life care to children?

**Methods**
This was a systematic mixed studies review\textsuperscript{17} following an integrated design\textsuperscript{18} to combine and synthesise quantitative, qualitative and mixed method study’s findings. Qualitative research is often portrayed as useful for elucidating new understanding of a phenomenon, while quantitative approaches are often depicted as more useful for elucidating what works. However, combining the two approaches increases the potential for identifying unexpected outcomes (Bryman, 2006).\textsuperscript{19} We chose to include quantitative and mixed-method research as we were looking not only at staff experience but also the impact of those experiences, in order to provide a more comprehensive understanding of health care professionals experience. The review recommendations outlined in the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) statement were followed for this review.\textsuperscript{20}

**Identification of relevant literature**

Six electronic databases, including CINAHL, MEDLINE, Web of Science, EMBASE, PsychINFO, and The Cochrane Library were searched in June 2015, with no date restrictions outside those of the databases. Searches used mesh terms when applicable and free text words, modified as appropriate for all databases. To ensure rigour, an information scientist in Queen’s University Belfast helped develop the search strategy. References were managed using Refworks. Additional literature was uncovered from searching reference lists of relevant studies retrieved from electronic searches, along with contacting experts in the field of paediatric palliative care. Table 1 presents the search method for Medline.

Table 1. Medline search strategy

| 1 | health personnel/ or allied health personnel/ or medical staff/ or nurses/ or nursing staff/ or personnel, hospital/ or physicians/ or volunteers/ |
Study criteria were established prior to searching the literature and were guided by the aims of the review. Peer-reviewed primary research studies, in English, using quantitative, qualitative or mixed method approaches were included. In order to make the review applicable to a broad, multiprofessional audience, we included different professional groups with differing levels of experience. This decision was also based on the increasing recognition of the value and need for multidisciplinary teams when delivering paediatric palliative care, rather than any one professional group in isolation.21 Studies were included if they considered the experience of health care professionals (specialist or non-specialist), including clinical, administrative and support staff, in any setting that delivered end-of-life care to children. Studies that included both patient and professional perspectives were only included if professionals’ views were presented independently. Studies were included if the findings clearly focused on staff experiences of providing end-of-life care to children. We excluded studies that did not provide any relevant findings on staff experience, such as staffs’ perceptions of quality end-of-life care, and end-of-life care educational programmes. Figure 1 describes the process of identifying and selecting studies as suggested by Moher et al.20 Searching electronic databases yielded a total of 1061 articles, with a further 25 articles identified from hand searching references. After removal of duplicates, this left a total of 964 articles. Title
and abstracts were screened using the eligibility criteria to ensure only those studies meeting the aim of the review were included. This left 55 studies which were assessed in full. Of these, 25 were rejected for not meeting the eligibility criteria, leaving a total of 30 studies included in the review.

Figure 1. PRISMA flow diagram

**Appraisal and data extraction.**
Each individual study was assessed for quality by two review authors using the Mixed Method Appraisal Tool (MMAT), a universally utilised, validated tool for mixed-method systematic reviews. Methodological quality was assessed using the relevant criterion for each method of investigation. Each included study was assigned a score based on the number of criterion met, along with a brief rationale for lower scores (see Table 2).

We used a previously piloted data extraction form to extract data on study aims, setting, participants, method and relevant findings. All stages of study selection, appraisal and data extraction were conducted by two independent researchers. Any discrepancies were discussed among the research team until consensus was achieved.

**Data synthesis.**

Data were analysed and synthesised using a systematic mixed studies review and integrative design. This approach enabled the grouping of data into findings focused on the same phenomenon rather than according to method. Descriptive thematic analysis was used to synthesise and analyse extracted data, following the stages set out by Whittemore and Knafl which included data reduction, data display, data comparison, conclusion and verification. Data reduction involved the extraction of data into a data extraction form, and data display involved summarising data in relation to staffs’ perspectives (Table 2).

</table>
Data comparison involved coding and condensing data relating to staff experience, impact of, and how they cope with providing end-of-life care to children, which were grouped according to patterns and themes. Data were also evaluated for contrasting outcomes or views within groups of data. The conclusion and verification stage involved identifying themes and sub-themes which were then described according to their relationships. Experiences were verified throughout the analysis stage by crosschecking primary sources in order to enhance credibility and reliability of the review findings.

**Results**

*Characteristics of included studies*

Thirty papers were included with publication dates ranging from 1989 to 2015. Studies were predominantly qualitative (n=18), with a smaller number of quantitative (n=6) and mixed-method studies (n=8). Five quantitative studies were cross-sectional, and one used a pre-post survey design. The majority of studies were conducted in the USA (10) with the remaining 21 studies carried out in the United Kingdom (6), Canada (3), Australia (2), Poland (1), Greece (1), Greece and Hong Kong (1), Sweden (2), Ireland (2), Finland (1), and Switzerland (1). The majority of studies considered nursing staff only (15), while others considered a wide range of health care providers collectively such as nurses, physicians, social workers, physiotherapists, psychologists and support staff (13), one included physicians only, and one support staff only. The majority of studies were conducted in a
The remaining studies were conducted across a range of settings such as hospital, hospice and community (3), community only (4) or hospice only (1). A summary of the aims, sample, setting, design and relevant findings from included studies are presented in Table 2.

*Review findings*

The first theme ‘Staff experiences’ highlighted the key experiences and challenges faced by a range of healthcare staff in a range of healthcare settings.

*Staff experiences*

**Rewards.** Despite the stress experienced, staff reported a number of rewards. The deep relationships that staff developed with children and their families were viewed as a major source of both personal and professional satisfaction, and ‘made the pain worth it’. Staff also reported feeling enriched from their work, and felt they gained a new perspective on life in relation to what was most important and meaningful. However, some sources of job satisfaction differed between doctors and nurses. For doctors, this related to controlling pain and providing efficient medical care to alleviate a child’s suffering, whereas for nurses psychosocial care and support for both dying children and their families was as important as providing physical care to the child.

*Professional boundaries.* The difficulty of maintaining professional boundaries was intricately linked to the length and intensity of relationships developed when providing end-of-life care to children. Staff defined this challenge as ‘walking the professional and personal line between family members and staff’. This challenge
appeared to be more pertinent to nurses, perhaps due to their more involved role with children and families. Nurses were acutely aware of the risk of becoming excessively or inappropriately involved with children and their families, and reported being viewed as a friend, or pseudo-member of the family rather than a professional care giver. Although nurses reported being taught the importance of professional boundaries in relation to not becoming overly ‘personal’ with patients, they felt it was difficult to follow these professional policies and feared being seen as unprofessional. Many nurses felt the need for professional boundaries contradicted the fostering of a therapeutic relationship and viewed it as a barrier to providing care and empathy to children and their families. However, some nurses felt it was important to avoid over involvement in order to cope and be able to take care of the other children in their care.

Work environment. The work environment had a significant impact on staff providing end-of-life care to children. For example, workload and inadequate coordination and communication between services presented additional challenges. Demanding caseloads, often due to staff shortages, meant staff did not have time to grieve or recover from experiencing a child’s death before they had to continue taking care of other children under their care, causing frustration and discontent. Not having time to meet a child’s needs beyond their clinical care in relation to interacting with the child, or taking time to just be with parents caused additional stress as staff felt this prevented optimal care. Further frustrations and feelings of guilt were reported in relation to not being able to provide follow-up bereavement support to families.

The hospital setting offered unique challenges for staff in relation to the culture of cure. Doctors struggled most when a child relapsed as this signalled the terminal
phase.\textsuperscript{31} Doctors highlighted the perception among newly qualified doctors that they ‘can cure everybody’, and their sense of disbelief when they realised they couldn’t.\textsuperscript{31}

*Length and depth of experience.* There appeared to be differences between healthcare professionals who dealt with end-of-life care on a more regular basis than those who were less familiar with this aspect of care. One study in a children’s hospital found that more experienced nurses and who had a higher level of palliative care education were more comfortable providing end-of-life care to children and their families.\textsuperscript{32} In contrast, nurses in community settings with less experience and education in relation to providing end-of-life care to children struggled with this role on both an emotional and professional level.\textsuperscript{47,48}

Challenges specific to community healthcare professionals included discharge planning, which they felt did not exist, was ill-planned, or happened too late, and as a consequence prevented the development of trust between staff and families.\textsuperscript{48} Furthermore, the vast number of agencies involved with the child’s care resulted in confusion surrounding roles, boundaries and responsibilities.\textsuperscript{48} Additional challenges included living and working in the same community which meant they were seen as a nurse at all times,\textsuperscript{11,48} and restricted support, with colleagues often living long distances away.\textsuperscript{48} The wide geographical area that had to be covered by small community teams also meant nurses felt unable to provide the level of support they would have liked to.\textsuperscript{48}

The hospice setting appeared to provide the most optimal work environment, with staff referring to its homelike qualities, lack of a rigid hierarchy and red tape, and time to spend with families so they could respond to individual children’s needs.\textsuperscript{12} Although communication between colleagues was evaluated as good by hospice
staff in one study,\textsuperscript{38} communication difficulties between colleagues, management and multi-disciplinary teams were referred to as a major source of stress in other studies within the hospital, community and hospice setting.\textsuperscript{9,6,12,38,44} This often led to lower job satisfaction,\textsuperscript{38} and discontinuity of care.\textsuperscript{25} The current system also presented challenges for hospice staff who felt referrals happened too late, mostly due to inadequate cross-sector understanding of availability and content of hospice care, and ineffective multi-disciplinary working.\textsuperscript{46} Those working in the voluntary sector were frustrated by the lack of government funding to assist them in providing services to children at the end of life and their families.\textsuperscript{28}

\textit{Most challenging experiences.} There were a number of experiences that appeared to be especially challenging when providing end-of-life care to children.

\textit{End-of-life decision making.} Both hospice and hospital staff reported end-of-life decision making and symptom management as extremely stressful.\textsuperscript{6,11,46} Deciding when end-of-life was near was referred to as an ‘invisible point in time when transition from curative to end-of-life treatment occurs’.\textsuperscript{6} This was exacerbated by parental distress in relation to withdrawing treatment.\textsuperscript{11,33,37,45,46} Nurses reported experiencing extreme moral distress and anxiety when families insisted on continuing interventions that they recognised were not in the best interests of the child.\textsuperscript{11,45,46}

\textit{Keeping silent.} An additional stressor related to parents’ efforts to shield their child from the truth about their impending death. This raised ethical concerns in relation to withholding information from children about their condition, thereby limiting the opportunities they had to give their views on care matters.\textsuperscript{6} Staff reported
experiencing guilt ‘just that feeling that I knew more than I had told them. It hurt knowing more about the child’s condition than could be revealed’.33

Communication with families. A range of staff, including doctors, nurses, social workers, psychologists, and physiotherapists all reported feeling anxious when talking with parents about death or using the word ‘dying’.26 Both doctors and nurses reported feeling at a loss for words,9,44,45 and as a consequence often avoided talking to parents.9 Children’s cancer nurses working in an acute hospital setting rated communication with parents as the highest perceived obstacle when providing end-of-life care to children.45

Impact on personal/professional life. Staffs’ experience of providing end-of-life care to children impacted on both their personal and professional lives.

Grief. The majority of studies showed that staff grieved over the death of a young patient, with findings from one study showing doctors exhibited higher levels of grief than nurses, and younger staff exhibited higher levels overall. Grief manifested in many similar ways across staff and settings, from depression,5,9 sadness,9,21,35,36,41,44,46 anger,21,31,35,44,46 emptiness/loneliness,35 irritability,5,11 decreased sex life,5 loss of appetite,21 sleep disturbance,11,12,21 anxiety,12,21 guilt,9,21,44 withdrawal,9,12,21,44 and having to take time off work.11 Staff also reported difficulties forgetting the child,36 being plagued by painful memories,29 and recurring thoughts about the child’s dying conditions and death.9,44

There were however differences between doctors and nurses in how they experienced grief. Although two studies of doctors and nurses working in paediatric oncology showed they both fluctuated between experiencing and avoiding grief,9,44 doctors reported more avoidance behaviour, such as avoiding going into the child’s
room when end-of-life was near, and not talking about their grief.\textsuperscript{44} Findings suggested that for doctors, grief over losing a young patient was a lonely experience, whereas for nurses it was a more social experience in terms of seeking support from their peers.\textsuperscript{44}

\textit{Disenfranchised grief.} All staff, including doctors, nurses, social workers, psychologists, and support staff in the hospital setting referred to their fears of grieving in public.\textsuperscript{9,29,31,33,36,39,41,44} Both doctors and nurses had anxieties around loss of their professional reputation\textsuperscript{31,39} and ability to support families if they revealed their feelings and grief.\textsuperscript{36} In the absence of any formalised support, staff felt they could not openly express their emotions and reported hiding in the bathroom to cry,\textsuperscript{35} or crying on the way home by themselves.\textsuperscript{29} While some nurses felt they were not supposed to grieve,\textsuperscript{41} others felt it was important to express their emotions in order for parents to feel more comfortable expressing theirs.\textsuperscript{33} However, the majority of staff felt they were required to put their grief to the side and return to work instantly, and had therefore no place to share their experiences.\textsuperscript{29} Staff not only hid their grief in the workplace, but also in their personal lives. Nurses reported feeling guilty about telling friends or family depressing stories\textsuperscript{40} and felt they had to be careful about sharing details of their work with others.\textsuperscript{39} Nurses spoke of the consequences of revealing their grief at home in relation to family members feeling uncomfortable and withdrawing from them.\textsuperscript{34} Doctors also reported feeling drained when they got home and as a consequence shut down or avoided contact with their own children and family members.\textsuperscript{31}

\textit{Coping strategies.} Staff reported a number of coping strategies which appeared to help them deal with the challenges of providing end-of-life care to children.
Finding meaning, finding closure. The importance of finding meaning and making sense of a child’s death was widely cited.\textsuperscript{9,21,33,39,40,44} For doctors, the death of a child acquired meaning when they had exhausted all possibilities and felt they had contributed to a good death in relation to control of physical symptoms.\textsuperscript{44} Nurses were able to find meaning in their involvement with the dying child’s comfort and support,\textsuperscript{44} along with supporting families.\textsuperscript{39}

Finding closure was also a recurrent theme in the literature, and appeared to aid the healing process for nurses in particular.\textsuperscript{34,35,40-42,45} Attending the child’s funeral helped bring a sense of closure to the special relationships built up with families,\textsuperscript{9,34,39,40} and nurses reported difficulty adjusting when unable to attend\textsuperscript{41,42} as they had no chance to say goodbye.\textsuperscript{33,39}

Self-care. A number of positive behaviours were mentioned as important for self-care, such as maintaining a sense of humour,\textsuperscript{12,21,35,41,42,45} regular exercise,\textsuperscript{31,39,41,42} meditation,\textsuperscript{41,42} time away from work/setting limits at work,\textsuperscript{41,42} healthy eating habits, massage,\textsuperscript{42} yoga,\textsuperscript{39} and seeking emotional support.\textsuperscript{46}

Distancing. Doctors and nurses reported distancing themselves from patients as a way of protecting themselves from becoming too involved,\textsuperscript{31,42} and for more experienced nurses to prevent burnout.\textsuperscript{30}

Recommendations for practice. A number of factors appeared to be important in terms of supporting staff when providing end-of-life care to children.

Education. All staff felt they lacked experience when communicating with both children and their families about end-of-life issues; this could lead to feelings of stress and inadequacy.\textsuperscript{29,36} Education was the highest associated variable for
improving confidence among nurses to provide end-of-life care in a children’s hospital,\textsuperscript{32} and the only modifiable factor for reducing death anxiety among paediatric nurses.\textsuperscript{27}

\textbf{Debriefing.} Debriefing was seen as important by most staff in relation to dealing with emotions,\textsuperscript{45,47} bringing closure,\textsuperscript{26,33} and sharing experiences.\textsuperscript{26} However, timing appeared to be crucial, as if too late could actually be detrimental ‘I may have found a ‘good place’ for that and all of a sudden, I’m back to the beginning’.\textsuperscript{34} While those working in the hospice setting were provided with formal debriefing, those in the hospital setting received more ad hoc support and felt this was detrimental to their emotional well-being and professional ability to provide quality care.\textsuperscript{46}

\textbf{Peer support.} Peer support was mentioned often as a major source of comfort.\textsuperscript{9,12,21,28,30,33,34,36,39,42,44} A wide range of staff experienced a great sense of relief from being able to discuss a child’s death with colleagues who understood what they were going through.\textsuperscript{30,34,40} Sharing their experience made it more bearable\textsuperscript{33} and provided an emotional outlet.\textsuperscript{9,44} However, doctors rarely sought support from colleagues.\textsuperscript{9,44}

\textbf{Organisational support.} There appeared to be great variation in the level of organisational support for staff. While staff in the hospice setting reported twice weekly staff group meetings with a visiting consultant psychiatrist\textsuperscript{12} staff in the hospital setting reported inadequate or no emotional, psychological or social support\textsuperscript{21,29,35,39} which left them feeling stressed and alone.\textsuperscript{29} Health and social care professionals emphasised the need for comprehensive occupational support to help them provide effective care, manage intense relationships with families, and for their own emotional well-being.\textsuperscript{46} A wide range of staff also highlighted the importance of
having time out to reboot emotionally, with a time frame of 15-30 minutes frequently mentioned.

**Common themes across hospital, hospice and community settings.** There were a number of common themes across the different care settings explored in this review. Staff across settings viewed the close relationships built up with children and their families as providing major personal and professional rewards. End-of-life decisions and symptom management were also cited as the most common challenges in both the hospice and hospital setting. Staff in all settings also experienced grief in similar ways after losing a child they had cared for. In terms of recommendations, staff across all settings emphasised the need for ongoing palliative care education, especially in relation to communicating with families about end-of-life issues.

**Discussion**

The findings from this review contribute to the understanding of the unique experiences of a wide range of healthcare staff who provide end-of-life care to children. Most studies focused on nurses which is not surprising given that nursing makes up the largest segment of healthcare providers. However, a large proportion considered a wide range of healthcare staff which is important considering that many different professionals, including doctors, social workers, psychologists, and support staff all play important roles in providing end-of-life care to children.

Results indicated that staff experience a number of rewards when providing end-of-life care to children that lead to increased job satisfaction. However, the work
environment had a negative impact on staffs’ level of job satisfaction, mostly in relation to inadequate multidisciplinary working and inadequate co-ordination between the many services involved in a child’s care. Staff also reported frustrations at resource barriers to providing emotional and spiritual care to children and their families, such as time to interact with the child, be with the parent, or providing follow-up bereavement care. Considering that job satisfaction amongst palliative care providers seems to be one of the key factors for improving the efficacy and quality of end-of-life care, it is imperative that those at policy and organisational level address the wider and immediate work conditions that cause staff distress.

As reflected in the literature, findings suggested that more difficulties arise in the hospital setting where the key focus is on short-term or acute cure. Doctors struggled to make end-of-life decisions, and both doctors and nurses felt unprepared to have end-of-life discussions with parents. Nurses also experienced moral distress over parents’ or other team members refusal to withdraw interventions that were not in the child’s best interests, and having to withhold the truth about their condition from the child; ultimately compromising the quality of care delivered. Continuity of care was also an area of contention, with staff feeling frustrated at the lack of provision for follow-up bereavement care.

Some major challenges, such as witnessing children’s’ suffering and death, communication with children and their families, and inadequate support have been well documented in the literature. However, the findings from this review also highlighted the challenges of maintaining professional boundaries in an area of healthcare that requires intense, often long term staff involvement.
Impact

Findings are supported by the wider literature showing that, while healthcare staff experience a diverse range of grief responses when a child under their care dies,\textsuperscript{9,35,51,52} as professionals they are not expected to display these emotions.\textsuperscript{53} As a consequence, they do not have the chance to mourn openly or receive sufficient support.\textsuperscript{54} Findings suggest staff may distance themselves as a protective measure, unintentionally compromising the quality of care provided to children and their families.\textsuperscript{55} Doka\textsuperscript{54} refers to this experience as disenfranchised grief, where healthcare staff cannot openly mourn, or receive social support because their loss is not acknowledged, even though findings from this review demonstrate that relationships developed with dying children and their families are intense and meaningful.

Coping strategies

In common with previous literature, findings suggested that support from professional colleagues is the most common strategy used for helping them cope when providing end-of-life care to children,\textsuperscript{51} often in the form of debriefing sessions which provided a safe place to share experiences with others who understood.\textsuperscript{52,56} However, as suggested by previous studies, debriefing may not be beneficial for all staff,\textsuperscript{57,58} and in some cases may actually prolong their grief if sessions happen too late after the death of a child. Findings from one hospice and one hospital setting provided models of good organisational support in the form of regular meetings with professionals who were adequately trained to support paediatric staff.
Recommendations for practice

Understanding staff experience of providing end-of-life care to children is essential for the development of support services, which based on the findings of this review should include: organisational support for ongoing education on paediatric palliative care, communication with children and their parents around death and dying, and how to manage professional boundaries without compromising patient care.

Communication between healthcare providers and patients is inherently difficult irrespective of the clinical setting, but even more so when providing care to children. However, as effective communication is so vital to connecting with the family, any lack of communication is likely to hamper care. The language used can hinder families understanding of the care being suggested. Beckstrand et al (p. 551) emphasised that the terminology used needs to be revised from terms such as ‘withdrawing or withholding to allowing death to naturally occur’.

Debriefing sessions should be timely, and delivered by professionals trained in children’s end-of-life care so they understand what their colleagues are going through. As doctors displayed the highest levels of grief, they should be encouraged to attend debriefing sessions to help break the culture of silent suffering that appears to permeate medicine. Staff with less experience also require additional support and education to increase their levels of comfort and competence when providing end-of-life care to children and their families.

As documented in the literature, staff attendance at funerals was shown to be beneficial, especially in relation to finding closure. As has been suggested by the findings of this review and the wider literature, staff should be facilitated to attend
funerals as part of their working hours, or paid to attend if during their off-duty time\textsuperscript{15,62} so they can continue to offer effective and compassionate care to the other children under their care.\textsuperscript{35}

At policy level, steps need to be taken to streamline services within paediatric palliative care, and to raise awareness of hospice services so that referrals are timely. This would help clarify community staffs’ roles and facilitate the development of trusting relationships with families, which is a cornerstone of quality end-of-life care.\textsuperscript{63}

\textit{Limitations}

This mixed method review confirms the lack of robust quantitative and qualitative studies relating to staffs’ experience of providing end-of-life care to children. As such, it is not possible to draw definitive conclusions. However, this review does highlight the gaps and limitations within the current knowledge base.

A strength of this review relates to the transferability of findings as included studies were conducted in many different countries, with a diverse range of healthcare staff in a diverse range of healthcare settings, yet showed more similarities than differences in relation to the impact of providing end of life care to children and the most important strategies to help support them.

\textbf{Conclusions}

Overall findings highlight the need for healthcare organisations to support and care for staff who provide end-of-life care to children, in the same way they expect their staff to support and care for their young patients. Ongoing education focusing on the
unique challenges of providing end-of-life care to children and the importance of self-care, along with timely multidisciplinary debriefing are key strategies for improving healthcare staffs’ experiences, and as such the quality of care they provide.

**Future directions for research**

As only one study focused on the experience of doctors individually, further research is required to increase the opportunity for greater acknowledgement and recognition that ‘emotional experiences do exist within the medical model of care’ (Kaplan p. 201). Furthermore, this review revealed the paucity of studies considering the individual experiences of support staff, or individual experiences of staff within the hospice setting. Further research should explore these neglected professional groups and settings so that *all* staff who provide end-of-life care to children can be supported to do so. Research exploring the effectiveness of interventions for mitigating healthcare staffs’ stress and grief experiences should also be a priority. In terms of reducing stress caused by the work environment, future research on effective models of multidisciplinary working within paediatric palliative care is required, along with how to improve co-ordination of services. Finally, a systematic review exploring key recommendations in relation to the most effective educational strategies and the most effective supportive strategies for staff providing end-of-life care to children is required.

**Contributions**
TM: developed the protocol for the review, identified and screened articles for inclusion, data extraction, data analysis and synthesis, and drafted the article. DS identified and screened articles for inclusion, data extraction, data analysis and synthesis, and critically revised the article. SP supervised the review, developed the protocol, data extraction, and critically revised the article. All authors approved the final version.
