Abstract—Children with Prader-Willi syndrome often exhibit challenging behavior in response to changes to routine. This phenomenon has been linked to a deficit in task switching ability which has been observed in children with the syndrome. TASTER is a cognitive training game which is being designed with input from a group of children with Prader-Willi syndrome, which aims to train task switching ability and thus reduce associated challenging behavior.

Keywords—human-centered design; serious games; Prader-Willi syndrome; cognitive training; task switching

I. INTRODUCTION

Prader-Willi syndrome (PWS) is a rare genetic disorder usually associated with mild to moderate intellectual disability (ID) and resistance to change [1]. In particular, temper outbursts due to changes to plans or routines have been linked to a deficit in task switching ability in individuals with PWS [2], [3], [4]. Video games have produced gains in specific cognitive processes in several typical and atypical populations [5]. Additionally, research in cognitive neuroscience has demonstrated a link between playing action video games (AVGs) and an increase in task switching ability [6], [7].

II. SPECIFIC APPLICATION

We are developing TASTER, a video game designed to train task switching in children with PWS. By increasing task switching ability, we aim to decrease occurrences of temper outbursts associated with changes to plans or routines. As such, our game aims to have a positive effect on clinically-significant behavior by targeting a specific cognitive impairment that has been linked to the behavior.

III. DESIGN AND DEVELOPMENT

It is essential that the game produced is tailored to the preferences and capabilities of children with PWS, who – due to cognitive impairments and behavioral traits associated with the syndrome – may not be capable of playing, or motivated to play, typical entertainment games. It is also important to fully utilize the insights afforded by the aforementioned research on the cognitive benefits of AVGs. Therefore, our iterative development process incorporates both human-centered design in the form of observational studies, and a domain analysis of AVGs. Observational studies took place before any design decisions had been made (using existing entertainment games), and will continue throughout development (using prototypes). The children can therefore be considered design informants [8].

A. Observational studies

1) Participants and procedure: Seven children with PWS (age 7 – 15; six female, one male) played a selection of existing games, in order to observe how they interacted with existing technology [8]. Children played the games during sessions lasting at least 30 minutes, with multiple sessions taking place over two weeks. To overcome difficulties faced by children with ID when expressing their preferences [9], most questions were presented as a forced choice between two alternatives, with images used where possible.

2) Results: Six children preferred playing games on a handheld tablet. Children preferred games in which they were tasked with collecting items (e.g. coins) (Table I), and preferred controlling games using simple touch gestures (Table II). Scores were calculated from responses to forced-choice questions comparing features; scores show the number of times a feature was preferred as a proportion of the total number of times the feature was considered.

The authors would like to thank the Foundation for Prader-Willi Research, for sponsoring the research.

B. Domain analysis

While AVGs show benefits in task switching ability, typical AVGs are not suitable for children with ID due to the complexity of the gameplay, the use of themes unsuitable for young children (e.g. violence) and the complexity of the control systems. The domain analysis aimed to identify features of AVGs that could be incorporated into a game suitable for children with ID, for example:

- Monitoring on-screen information during gameplay.
- Adapting goals due to unforeseen circumstances.
- The presence of distracting stimuli which must be filtered and ignored.

C. Conceptual design

A game was designed in which players must control a character to collect items (the preferred gameplay identified during observational studies). The items are creatures which can be identified in terms of their color (red or blue) or shape (cuboid or pyramid) (Fig. 1). Players must collect only one kind of creature at a time, with the current target specified as either a shape or a color; by changing how the target is specified, players are forced to switch how they conceptualize the creatures (the task switch). The game incorporates the three features of AVGs mentioned above: information panels and messages are displayed on screen; large rocks, which must be avoided, appear at random intervals in the player’s path; and distracting stimuli occur in the form of sound effects, particle effects, and a screen shake effect. The player’s character is controlled by touching the screen at the location which they wish to move to, in line with the preference for simple touch controls expressed by children in observational studies.

D. Prototype

A prototype game was developed for handheld tablets, the preferred distribution platform of the children who took part in the observational studies.

E. Playtesting

1) Participants and procedure: To date, five children with PWS (age 7 – 15; three female, two male) have tested the game. Children played the game for at least 30 minutes, and answered questions designed to gauge the usability of the prototype, their motivation to play it and their level of comprehension of the gameplay.

2) Results: Initial results show that players achieve a high level of satisfaction from the game, are motivated to play it, and find the interface and gameplay easy to understand.

IV. Conclusion

Children with ID can play the role of design informants [8] in the design of cognitive training games. Furthermore, the design of serious games in general can benefit from analysis of entertainment games, to identify features that might contribute to the effectiveness of the serious game.
