decided to analyze the rate of progression of CKD in a population followed by a multidisciplinary team.

Methods: We analyzed data from 209 patients (102 females) referred to the Nephrology Division, after at least 6 months under treatment by a multidisciplinary team (nephrologist, nutritionist, nurse and psychologist). Patients were followed from January of 2002 until December of 2005. Glomerular filtration rate was estimated by MDRD equation (eGFR). Patients with eGFR below 15 ml/min were excluded, and this value was considered the end-point for calculation of the rate of decline of renal function. Results are means ± SD.

Results: Hypertension was the main cause of CKD (31%) followed by Diabetes (26%). Age was 60 ± 15 years, body mass index was 27 ± 5 kg/m^2 for females and 26 ± 4 kg/m^2 for males. Serum calcium, phosphorus and albumin were normal. Urea was 71 ± 36 mg/dl, eGFR = 38 ± 20 ml/min. Systolic arterial pressure was 137 ± 20 mmHg and diastolic pressure 80 ± 11 mmHg; hematocrit = 37 ± 5%; hemoglobin = 12.3 ± 1.7 g/dl; cholesterol = 194 ± 42 mg/dl; HDL-cholesterol = 36 ± 11 mg/dl; LDL-cholesterol = 119 ± 54 mg/dl; triglyceride = 167 ± 106 mg/dl; iPTH= 221 ± 221 pg/ml.

From the studied population 58% was referred with eGFR = 45-30 ml/min, and the remaining with eGFR = 29 to 15 ml/min.

K/DOQI suggests a decline of 4 ml/min/year for CKD patients. As shown in Table 1, the rate of decline of eGFR of the present population was below this level, meaning an extra gain of time per year free from dialysis as a consequence of the conservative management with a multidisciplinary team.

Conclusions: The present data show that a late referral population, did not show complications of uremia, and the rate of decline of GFR was lower than suggested by K/DOQI. We concluded therefore, that, if followed by specialists and if possible by a multidisciplinary team, retarding the progression of CKD even in its more advanced stages is possible. Therefore conservative management is an efficient way to maintain CKD patients and to postpone renal substitutive therapy. Finally we believe that programs aiming this treatment should be encouraged to ameliorate care of CKD patients.

Epidemiology of CKD 1

FP158 ETHNIC DIFFERENCES IN PREVALENCE OF HEMATOLOGICAL AND METABOLIC ABNORMALITIES BY GFR STAGE

S. Babour 1, L. Ev 2, O. Djindjiev 2, M. Karim 3, A. Levin 1, 1 Division of Nephrology, University of British Columbia, Vancouver, BC, Canada; 2 Health Care and Epidemiology and BC Renal Agency, University of British Columbia, Vancouver, BC, Canada; 3 Royal Imperial Hospital, Vancouver, BC, Canada

Introduction and Aims: Biochemical and hematological abnormalities increase in severity and prevalence by stage of GFR. The evidence to date is based on NHANES data from a US cohort of white, black and Hispanic ethnicities. Using a provincial database in which all patients referred nephrologists are registered when GFR < 60 ml/min, we undertook to describe the prevalence of abnormalities by ethnicity within different levels of GFR.

Methods: British Columbia is a population of 4 million people, with mixed ethnicities including Caucasian, Oriental Asian, South Asian and First Nations individuals. Between 2000 and 2006, we examined a registered cohort of 5968 pts who had GFR < 60 ml/min/1.73 m^2, to determine the prevalence of abnormalities in hemoglobin, calcium, phosphate, iPTH, albumin and bicarbonate at the time of registration. Cut-off-points were selected based on the lower or upper limit of the lab normal range. GFR was calculated using the abbreviated MDRD formula, and using categories of <15, 15-30, 30-45 and 45-60 ml/min.

Results: The mean age of our cohort was 66%; 57% were male, and 38% were diabetic. The proportion of patients within each category of GFR was similar by ethnicity: Caucasian 65-77%, Asian Oriental 8-17%, South Asian 7-10%, Other 3-6%. Table 1 describes the prevalence (%) of abnormalities of hematological and metabolic abnormalities by ethnicity and level of GFR. Note that there is statistically different prevalence of abnormalities within stages of GFR between Caucasians and Asian Orientals in particular.

Conclusions: This is the first report of differential prevalence of well-known renal associated abnormalities by ethnicity within a patient cohort in a universal access health care system. Improved understanding of these differences are important in order to understand the paradoxical finding of better prognosis for Asian Orientals on dialysis. These findings indicate that this occurs in spite of worse metabolic and hematologic abnormalities at earlier stages of CKD. Questions around race specific GFR and related laboratory test cut-offs should be pursued.

FP158 PREDICTORS OF NEW-ONSET KIDNEY DISEASE IN A GENERAL MIDDLE-EUROPEAN POPULATION

Rudolf P. Oberrmayr 1, Christian Temml 2, Maarten Knechtelsdorfer 1, Georg Gutjahr 1, Josef Kletzmayr 1, Susanne Heiss 1, Renate Klausner-Braun 1, 1 Dono hospital in der Sozialmedizinischen Zentrum Ost der Stadt Wien, 2nd Medical Department, Vienna, Austria; 2 Department of Health Prevention, Vienna Medical University, Institute for Statistics and Probability Theory, Vienna, Austria

Introduction and Aims: Established cardiovascular risk factors are associated with end-stage renal disease (ESRD) with hypertension and diabetes being the leading causes. The aim of this study was to identify risk factors at an earlier stage of kidney disease with the belief that interventions could prevent or delay the progression to ESRD as well as cardiovascular disease. Predictors of new-onset kidney disease have not been thoroughly studied.

Methods: Since 1990 the general population of Vienna was invited to yearly preventive medical checkups within the ongoing Vienna Health Study. Until 2005, 24,689 apparently healthy volunteers (44% women, age range 20-84 years, men 20-89 years) could be assessed longitudinally. They performed a baseline examination at any time within the study period and were subsequently invited to a follow up examination once a year,
but no preset time intervals for the follow up examinations could be demanded imperatively. Within the follow up period, there were a mean of 3.09 individual follow up examinations performed, each individual's mean follow up period was 5.66 years and the mean longest follow up period was 7.44 years. Primary outcome of interest was the development of kidney disease defined as a decrease of glomerular filtration rate (GFR) < 60 ml/min/1.73m² (calculated by the abbreviated Modification of Diet in Renal Disease (MDRD) equation) at the follow up examinations. Covariates included age, sex, GFR, body mass index, sports (endurance exercise ≥ 2 times/week), smoking status, total-, HDL-, LDL-cholesterol, triglycerides, uric acid, fasting serum glucose, systolic and diastolic blood pressure, diagnosis of hypertension categories, and diabetes mellitus. A multivariable logistic generalized estimating equations model (taking into account the dependence between repeated measurements within the same individual at different follow up periods) was performed with respect to statistical significance resulting from univariate analysis of the covariates adjusted for age and sex. Variables were retained if Wald tests gave a P < 0.001.

Results: The following parameters presented as odds ratios (OR) with 95% confidence intervals predicted new-onset kidney disease: Age (increase of 5 years), OR=1.35 (1.33 to 1.37); sex if female, OR=1.91 (1.70 to 2.16); MDRD-GFR ≥ 90 ml/min/1.73m² vs. 80–89 ml/min/1.73m², OR=0.54 (0.50 to 0.73); sports, OR=0.64 (0.57 to 0.73); smoker, OR=1.69 (1.54 to 1.85); ex-smoker, OR=1.38 (1.22 to 1.56); uric acid (increase of 2 mg/dl), OR=1.71 (1.60 to 1.83); hypertension stage 1, OR=1.78 (1.60 to 1.99); hypertension stage 2, OR=2.28 (1.99 to 2.61); diabetes mellitus, OR=1.52 (1.11 to 2.10).

Conclusions: Established cardiovascular risk factors predicted new-onset kidney disease. The impact of sex should be interpreted retentive, since sex appears in the numerator of the MDRD-equation. Higher GFR at baseline and sports were revealed as probably protective.

**FP160 CHRONIC KIDNEY DISEASE AND MORTALITY AND MORBIDITY AMONG PATIENTS WITH ESTABLISHED CARDIOVASCULAR DISEASE: A COMMUNITY-BASED COHORT STUDY**

Liam Glynn 1, Donal Reddan 2, John Newell 3, John Hinde 1, Brian Buckley 1, Andrew Murphy 1, 1Department of General Practice, National University of Ireland, Galway, Ireland; 2Department of Nephrology, National University of Ireland, Galway, Ireland; 3Department of Mathematics, National University of Ireland, Galway, Ireland

**Introduction and Aims:** The importance of chronic kidney disease as an independent risk factor for morbidity and mortality in patients with cardiovascular disease in the community is not widely recognised.

**Methods:** A retrospective cohort study based in the West of Ireland followed a randomised practice-based sample of patients with cardiovascular disease. A database of 1,609 patients with established cardiovascular disease was established in 2000. This was generated from a randomised sample of 35 general practices in the West of Ireland. The primary end point was death from any cause. The secondary endpoint was a cardiovascular composite endpoint which included death from a cardiovascular cause or any of the following: death from CVD or stroke.

**Results:** A database of 1,609 patients with established cardiovascular disease was generated from a randomised sample of 35 general practices in the West of Ireland. The primary end point was death from any cause. The secondary endpoint was a cardiovascular composite endpoint which included death from a cardiovascular cause or any of the following: death from CVD or stroke.

**Conclusions:** Established cardiovascular risk factors predicted new-onset kidney disease. The impact of sex should be interpreted retentive, since sex appears in the numerator of the MDRD-equation. Higher GFR at baseline and sports were revealed as probably protective.
Background

Although MS is known to be strongly associated with CKD in several cohort studies from different countries, it is not known which components of MS are more important than others for the development of CKD or which host factors play a significant part in the relationship between MS and CKD. To better understand the complex interrelationship between MS and CKD, we performed a cross-sectional study in non-institutionalized Korean civilian using the data of Korean NHANES in 2001. The Korean NHANES was a cross-sectional survey of a nationally representative sample of the Korean population.

Methods

Of 7,918 participants, 5,491 at age between 20 and 79 years were available for analysis for the prevalence of CKD (defined as dipstick proteinuria or a reduced GFR less than 60 ml/min per 1.73m² by MDRD formula). MS was diagnosed by NCEP-ATP III with the Asia-Pacific abdominal obesity criteria (90 cm for men, 80 cm for women).

Results

The prevalence of CKD was in 8.7% of subjects (7.2% in men and 9.9% in women) and MS was seen in 25.7% (24.4% in men and 26.8% in women). The prevalence of CKD increased with age, especially in 60 years of age and over sharply in both genders. Although MS was a significant predictor of CKD in women (OR=2.49 (1.50 to 4.12, p=0.000) in men and 60, OR=1.04 (0.59 to 1.82, p=0.89) in men<60, OR=1.09 (0.69 to 1.72, p=0.73) in women<60, OR=1.44 (0.95 to 2.17, p=0.08) in women>60). This finding suggested that MS is no more a significant determinant of CKD after age of 60 despite a high prevalence of MS per se in this age group. Among five risk factors of MS, all five components affected CKD in men<br>≤60 years (impaired fasting glucose: OR=2.05 (1.00 to 4.16, p=0.05), high TG: OR=2.69 (1.71 to 4.25, p=0.000), hypertension: OR=2.65 (1.70 to 4.11, p=0.000), central obesity: OR=2.41 (1.54 to 3.77, p=0.000), low HDL: OR=1.67 (1.08 to 2.58, p=0.02) whereas only central obesity, hypertension and high TG related to CKD in women<60 years (central obesity: OR=1.60 (1.13 to 2.27, p=0.008), hypertension: OR=1.80 (1.22 to 2.66, p=0.003), high TG: OR=1.50 (1.02 to 2.20, p=0.04)).

Conclusions

Metabolic syndrome was a significant determinant of CKD in younger subjects (<60 years), not in elderly population. In men, all five risk factors of MS were important, but in woman, only central obesity, hypertension and high TG were significant risk factors for CKD. In elderly population, not MS but aging and other risk factors may take more important part in the development of CKD.
undergoing non-emergent cardiac catheterization at a single institution were also evaluated for atherosclerotic RAS by renal angiography. Clinical, laboratory and angiographic data were recorded. Ps enrolment will end by April 2007.

**Results:** We studied 682 consecutive pts who underwent coronary angiography and renal arteriography (age 63±11 yr, M 494 P 188, Scr ±0.3 mg/dL, CrCl 87±31 ml/min, Diabetes 36%, Hypertension 87%, Hyperlipidaemia 75%). In the aggregate, 49 patients out of 682 (7%) had a significant RAS (>50%) and 505/682 (74%) had at least 1 coronary vessel involved (1 vessel in 172 cases, 2 vessels in 168 cases and 3 vessels in 165 cases). On univariate logistic regression analysis, RAS was significantly associated to the severity of CAD (of a coronary vessel involved (P<0.001)), history of peripheral vascular disease (P<0.001), CrCl (P<0.001), serum creatinine (P<0.001), history of chronic renal insufficiency (P<0.001), hyperlipidaemia (P=0.007), pulse pressure (P=0.008), age (P=0.01), systolic pressure (P=0.03), and BMI (P=0.05). No significant association was found between renal artery stenosis and sex, smoking and diabetes. In a multiple logistic regression model, including all univariate correlates of RAS, serum creatinine (odds ratio (OR) (1 mg/L increase): 6.95, 95% CI: 3.19-15.16, P<0.001), peripheral vascular disease (OR: 2.75, 95% CI: 1.38-5.49, P=0.004), hyperlipidaemia (OR: 3.00, 95% CI: 1.03-8.77, P=0.04) and number of involved coronary vessels (OR [1 stenotic vessel increase]: 1.39, 95% CI: 1.02-1.89, P=0.04) maintained an independent association with RAS. In a ROC curve analysis serum creatinine, peripheral vascular disease, hyperlipidaemia and number of involved coronary vessels jointly produced a ROC curve area of 78.8% (95% CI: 72.2-85.4%, P<0.001). In this analysis, the contribution of the number of involved coronary vessels to identify RAS was very low (2.4%). Accordingly, the estimated probability of significant RAS, adjusted for the above mentioned significant covariates, associated with 0,1,2,3 CAD-vessels was 3%, 4%, 6% and 8%, respectively.

**Conclusions:** In a population at high risk for cardiovascular disease, not previously suspected of having RAS, the latter is associated with simple and readily determined clinical and laboratory characteristics. These data may facilitate the selection of patients who may have to undergo to diagnostic renal angiography procedures.

---

**FP165 MORTALITY RISK FOR PATIENTS RECEIVING HEMODIALYSIS VERSUS HEMODIALYSIS: RESULTS AT TWO YEARS FROM THE RISCAVID STUDY**

Vincenzo Panichi, Giovanni Manca Rizza, Sabrina Pasletti, Emanuela Mantuan, Raffaele Caprioli, Valentina Marchetti, Sara Beati, Erica Panicucci, Cristina Consani, Alessandro Antonelli, Giacomo Donati, Roberto Bigazzi, Giuliano Barsotti, Paolo Rindi, Mauro Aloisi, Roberto Palla. RISCAVID Study Group, North-West Tuscany, Italy

**Introduction and Aims:** RISCADIV (Cardiovascular risk in dialysis) study is an observational and prospective study of the over 800 patients in hemodialysis and peritoneal dialysis of the north-west part of Tuscany. This population is rather peculiar because hemodialfiltration (HDF) is largely used for renal replacement therapy (44%). Characteristics and outcomes at two years were compared for patients receiving HDF versus HD.

**Methods:** The study followed 757 patients stratified into three groups: standard bicarbonate HD (n.424), and low- and high-efficiency HDF (n.128). At the time of the enrolment demographic, clinical and laboratory data of the whole population were registered as well as co-morbidity conditions established by anamnestic and instrumental information. The population was followed up for 24 months reporting overall mortality, CV mortality and CV major non fatal events (acute myocardial infarction, stroke and itus). Cox proportional hazards regression assessed adjusted differences in mortality risk.

**Results:** Patients receiving standard HD had an higher incidence of diabetes (21.6% vs 16.4% low-eff. HDF vs 16.0% high-eff HDF); patients receiving low and high-efficiency HDF had significantly longer average duration of end-stage renal disease (6.5 and 6.3 versus 5.3 years), patients receiving high-efficiency HDF had significantly more hypertension (60 versus 45% low-eff HDF). No significant differences were observed in received single-pool Kt/V (1.40 vs 1.43 at 1.40). High-efficiency and low-HDF patients had lower crude mortality rates than standard HD patients. After adjustment, high-efficiency and low HDF patients had a significant lower mortality risk than those receiving standard HD (relative risk=0.78, P=0.01).

**Conclusions:** These observational results at two year from the RISCADIV study confirm recent findings that HDF may improve patient survival independently of its higher dialysis dose.

---

**FP166 IDENTIFYING INDIVIDUALS WITH CKD: ARE WE OVERESTIMATING THE NUMBER?**

Laura Clark 1, Gordon Prescott 2, Nicholas Fluck 1, Cairns Smith 1, William Simpson 1, Alison Macleod 1. 1Medicine and Therapeutics, University of Aberdeen, Aberdeen, United Kingdom; 2Public Health, University of Aberdeen, Aberdeen, United Kingdom; 4Clinical Biochemistry, NHS Grampian, Aberdeen, United Kingdom

**Introduction and Aims:** Chronic kidney disease (CKD) is becoming increasingly common in the community as a result of our ageing population and rising incidence of diabetes. In recognition of this the Quality Outcomes Framework for CKD has been developed allowing us to identify “at risk” individuals at a much earlier stage and target management strategies. Despite this, little is known about the epidemiology and natural history of early CKD, particularly disease progression, and precisely what impact these individuals will have on the health service.

We aimed to establish with increased accuracy the prevalence and severity of CKD in a selected population with at least one abnormal creatinine in North-East Scotland.

**Methods:** In a linked study we identified 5751 patients with at least 1 creatinine ≥150umol/l (males) and >130umol/l (females) in a 6 month period using the single laboratory that serves Grampian (pop.500,000). Using the criteria of 3 abnormal creatinines, at least one month apart, revealed that 2315 had CKD. 474 had ARF and 88 ACRF using ADQI definition. 1918 patients, however, could not be classified. 1405 of these have been analysed to date. All available creatinines (median N=27) were converted to eGFR using the abbreviated MDRD formula. eGFRs were grouped into 3 time periods: Index, Previous and Future. Using median eGFR values patients were grouped according to their likelihood of having CKD. The breakdown of groups are as follows: Unlikely n=80 (5%), Uncertain=245 (17%), Probable n=933 (66%), insufficient data n=147(10%). The presence of markers of kidney damage, co-morbidities and outcomes were identified from case note review.

**Results:** The median age was 78 and 80 for males and females respectively. Median eGFR was 33.4 for females and 38.7 for males. Those in the “at risk” group were initially staged according to their index eGFR. Markers of kidney damage determined from case note review allowed a further 61 patients to be staged (994 in total). Of these, 82% are in Stage 3, 17.7% Stage 4 and 0.3% in Stage 5. Hypertension and ischaemic heart disease were the most common co-morbidities. Mortality in Stage 3 was 45% at 30-36 months. Median survival from time of index was 1.4 years for Stage 4 and 0.4 years for Stage 5. 131 patients in the “at risk” group without markers were classed as having no definite evidence of CKD (5% of 1405). The remaining 336 patients had insufficient data for classification (25% of 1405).

**Conclusions:** The majority of patients with at least one elevated creatinine (70%) in this study have evidence of CKD. This predominantly elderly population if referred to the renal services are likely to utilise a significant proportion of our health care resources. On the other hand a substantial minority (30%) have no conclusive evidence of CKD. These patients may have been included in other prevalence studies thus overestimating the prevalence of CKD.
CEREBROVASCULAR DISEASE HAS INCREASED INCIDENT END STAGE RENAL DISEASE (ESRD).

Methods: This is a post hoc, cross-sectional study including 210 ESRD stage 5 patients close to the start of dialysis therapy, with a follow-up of up to 60 months. Biochemical measurements of total and free forms of thyroid hormones, s-albumin, hs-CRP, plasma interleukin (IL)-6, soluble vascular adhesion molecule-1 (sVCAM-1), insulin-like growth factor 1 (IGF-1) and 8-hydroxy-2’-deoxyguanosine (8-OHdG) were performed.

Results: Multivariate analysis according to receiver operating characteristic (ROC) curves, showed that among the hormones studied (total and free forms), mortality was best predicted by total triiodothyronine (T3). When using the cut-off levels derived from ROC, low T3 levels were associated with increased inflammation (higher concentration of hs-CRP, IL-6 and sVCAM-1), increased oxidative stress (higher concentration of 8-OHdG) and wasting (lower concentration of s-albumin and IGF-1). Finally, low T3 was associated with worse all-cause (Likelihood ratio= 35.9; p=0.0001) and cardiovascular mortality (Likelihood ratio= 37.6; p<0.0001) after adjustment for age, gender, presence of diabetes mellitus and inflammation.

Conclusions: This study shows that low thyroid hormone levels are associated to increased inflammation, wasting and oxidative stress markers in ESRD patients. This study is also able to compare and propose for the first time, T3 levels as a more sensitive prognostic factor than T3 of not only all-cause but also CVD mortality in ESRD patients. Altogether, the present study supports the hypothesis that thyroid dysfunction is implicated in the high mortality risk of the ESRD population.

Supported by an ERA-EDTA grant.

FP169 MODERATE REDUCTION OF PRE OP GFR IS ASSOCIATED WITH POORER PROGNOSIS IN PATIENTS UNDERGOING GENERAL SURGERY

Adalbert Schiller 1, Dora Valceanu 2, Ana Maria Sararu 2, Adelina Mihacescu 1, Oana Constantinescu 1, Agata Borcanea 2, Nicu Olarui 1, 2, *Nephrology, Emergency Clinical Hospital, Timisoara, Timis, Romania; 2General Surgery, Emergency Clinical Hospital, Timisoara, Timis, Romania; *Nephrology and Dialysis, Emergency Clinical Hospital, Bucharest, Romania

Introduction and Aims: The aim of this study was to evaluate the effects of decreased GFR on post op prognosis of patients undergoing general surgery interventions.

Methods: We investigated 942 randomly assigned patients to this study (442 male, 500 female, average age 55.68±16.31 years) needing general surgery intervention. History for previous renal disease (renal function investigations) for hypertension (HT) and for diabetes mellitus (DM) was investigated. There have been followed up: blood pressure, haemoglobin, fasting blood glucose, urine output, serum creatinine, GFR (MDRD 4), criteria for sepsis and the survival of the patients. Data have been processed using the R Package statistical software. The t-test and the Fisher exact test were used for two-group comparisons and multiple regression analysis to evaluate influence of biological data on post op outcome.

Results: Patients have been divided into two groups: group 1 - pre op GFR <60 ml/min/1.73m², 24.73% of the cases (average GFR = 44.43±13.06 ml/min/1.73m²) and group 2 - pre op GFR >60 ml/min/1.73m², 75.27% of the cases (average GFR 93.71±33.74 ml/min/1.73m²). In group 1 patients presented significantly higher average age (65.48±11.36 vs. 52.47±16.41 years - p<0.0001) and higher prevalence of DM (52.36% vs. 30.18% - p<0.0001). Concerning the complications, the prevalence of sepsis and of ARF (according to RIFLE criteria) was significantly higher in the first group (9.87% vs. 2.96% - p<0.0001) and (30.04% vs. 3.94% - p<0.0001). 18.02% of the patients died in the post op period in group 1 as compared to 4.79% in group 2 (p<0.0001). The post op outcome was influenced by age of the patients the presence of ARF, of sepsis of high fasting blood sugar and low systolic blood pressure and not by the other clinical and biological data that have been followed up. There was an extremely strong dependency between ARF and low pre op GFR and we interpret these latter results as a direct consequence this fact.

Conclusions: Our analysis suggests that even moderate reduction of pre op GFR in patients undergoing general surgery is a risk factor for the development ARF and sepsis and a poor post op prognosis predictor.

FP170 INCIDENT END STAGE RENAL DISEASE (ESRD), MORTALITY AND PREDICTORS OF RENAL DEATH IN CKD PATIENTS REGULARLY FOLLOWED IN NEPHROLOGY: FOLLOW UP OF THE TARGET BLOOD PRESSURE LEVELS (TABLE) COHORT

Luca De Nicola 1, Roberto Minutolo 1, Paolo Chioldini 1, Carmine Zoccali 2, Silvio Borrelli 3, Raffaele Scigliano 1, Vittorio Siroli 2, Cataldo Abaturovso 1, Andrea Pota 2, Alessio Montanaro 1, Paolo Monardo 1, Domenico Santoro 1, Antonina Messina 9, Vincenzo Bellizzi 10, Giuseppe Conte 1, for the TABLE Study Group. 1Div. of Nephrology, CNR in Reggio Calabria; 2University of Chieti; 3University of Verona; 4University Federico II in Naples; 5Hospital in Martina Franca; 6University of Messina; 7University of Catania; 8Hospital of Solofra, Italy

Introduction and Aims: In US and North Europe cohorts of CKD patients regularly followed in nephrology the incidence of ischaemic stroke is high in pre-dialysis CKD patients. The prevalence of stroke is significant even in the early stages of CKD. Markers of inflammation, proteinuria, haemoglobin, and the level of renal function were the most significant risk factors for the occurrence/recurrence of stroke and for cerebral vessels remodelling.

Methods: We investigated 942 randomly assigned patients to this study (442 male, 500 female, average age 55.68±16.31 years) needing general surgery intervention. History for previous renal disease (renal function investigations) for hypertension (HT) and for diabetes mellitus (DM) was investigated. There have been followed up: blood pressure, haemoglobin, fasting blood glucose, urine output, serum creatinine, GFR (MDRD 4), criteria for sepsis and the survival of the patients. Data have been processed using the R Package statistical software. The t-test and the Fisher exact test were used for two-group comparisons and multiple regression analysis to evaluate influence of biological data on post op outcome.

Results: Patients have been divided into two groups: group 1 - pre op GFR <60 ml/min/1.73m², 24.73% of the cases (average GFR = 44.43±13.06 ml/min/1.73m²) and group 2 - pre op GFR >60 ml/min/1.73m², 75.27% of the cases (average GFR 93.71±33.74 ml/min/1.73m²). In group 1 patients presented significantly higher average age (65.48±11.36 vs. 52.47±16.41 years - p<0.0001) and higher prevalence of DM (52.36% vs. 30.18% - p<0.0001). Concerning the complications, the prevalence of sepsis and of ARF (according to RIFLE criteria) was significantly higher in the first group (9.87% vs. 2.96% - p<0.0001) and (30.04% vs. 3.94% - p<0.0001). 18.02% of the patients died in the post op period in group 1 as compared to 4.79% in group 2 (p<0.0001). The post op outcome was influenced by age of the patients the presence of ARF, of sepsis of high fasting blood sugar and low systolic blood pressure and not by the other clinical and biological data that have been followed up. There was an extremely strong dependency between ARF and low pre op GFR and we interpret these latter results as a direct consequence this fact.

Conclusions: Our analysis suggests that even moderate reduction of pre op GFR in patients undergoing general surgery is a risk factor for the development ARF and sepsis and a poor post op prognosis predictor.
selected from the general population, incidence of death is 2 to 5 times greater than that of ESRD and associated with CKD severity. Whether the same holds true in tertiary nephrology care is unknown. We evaluated outcome and determinants of renal death in the Italian TABLE cohort of CKD patients.

**Methods:** Large prospective cohort was constituted enrolling all consecutive patients attending 26 renal clinics during a 6-month period of 2002/03 that had diagnosis of CKD, GFR <60 mL/min/1.73 m² (no dialysis-no transplant) and Nephrology care from >6 months. Follow up for renal death (all-cause death, ESRD) ended at 11/30/06. Survival analysis was performed by means of incidence rates and Cox regression model.

**Results:** Out of 1353 patients screened, 1269 met selection criteria (stage 3, 4, 5: 596, 504, 169). At baseline age was 66±14 y, males 57%, diabetes 28%, cardiovascular (CV) disease 31%, GFR 30.4±13.8 mL/min/1.73 m², systolic blood pressure (SBP) 139±18 mmHg, total cholesterol (TC) 199±42 mg/dL, haemoglobin (Hb) 12.5±1.8 g/dL, proteinuria 1.03±1.43 g/day. CEI or ARB were prescribed in 72% of patients, statin in 21% and epoietin in 13%. During a median follow up of 30 months, 258 patients reached ESRD while 150 died (72% for CV cause) with incidence rates of 8.8 versus 5.1/100 pts/yr (Figure). Cox model (hazard ratio and 95% confidence interval) showed that age (1.02, 1.01-1.02, P=0.001), diabetes (1.26, 1.00-1.60, P=0.049), CV disease (1.57, 1.24-1.97, P=0.0001), and proteinuria (1.14, 1.08-1.21, P<0.0001) predicted renal death, while a protective role was found for GFR (0.93, 0.92-0.94, P<0.0001), Hb (0.92, 0.85-0.98, P=0.015) and statin prescription (0.61, 0.47-0.87, P=0.004). Gender, SBP, TC, and use of CEI/ARB were not significant.

**Conclusions:** In CKD patients followed in Italian renal clinics, mortality is less frequent than ESRD and does not increase with worsening of CKD. Discrepancy with previous studies may be due to the tertiary care setting and the lower background Italian population CV mortality. Under these conditions, renal survival can be improved by larger use of statins and more intensive treatment of proteinuria and anemia.

**FP171 ASSOCIATION OF METABOLIC SYNDROME AND CHRONIC KIDNEY DISEASE (CKD) IN KOREA: RESULTS FROM KOREAN NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY (KOREAN NHANES)**

**Introduction and Aims:** CKD is now a worldwide epidemic, which is possibly due to the continuous increase in the prevalence of MS. MS has been shown to be strongly associated with CKD in several cohort studies from different countries. Incidence of end stage renal disease (ESRD) in Korea is increasing more than 10% annually, which takes the 11th rank in the world according to USRDS in 2006. Early detection and treatment of the risk factors for CKD have a paramount importance to reduce the incidence of ESRD. To better understand the clinical implication of MS as a risk factor of CKD and its characteristics which is possibly different in each countries with different ethnic background and life style, we performed a cross-sectional study in non-institutionalized Korean civilian using the data of Korean NHANES in 2001.

**Methods:** Of 7,918 participants, 5,491 at age between 20 and 79 years were available for analysis for the prevalence of CKD (defined as dipstick proteinuria or a reduced GFR less than 60 mL/min per 1.73 m² by MDRD formula). MS was diagnosed by original NCEP-ATP III criteria (waist circumference, 102 cm for men and 88 cm for women, NCEP-0) or NCEP-ATP III with the Asia-Pacific abdominal obesity criteria (90 cm for men, 80 cm for women, NCEP-AP).

**Results:** Overall, 33.9%, 16.2%, 33.1%, 49.0%, 9.9% and 33.6% of the participants had elevated blood pressure, high plasma glucose, high triglyceride, low HDL-cholesterol and abdominal obesity by NCEP-O and NCEP-AP, respectively. The prevalence of MS was 18.0% by NCEP-O and 25.7% by NCEP-AP. CKD was seen in 8.7% of subjects. In subjects with MS, the prevalence of CKD was higher (18.3 vs. 6.7%, p=0.0001) with a lower GFR (74.2 vs. 80.1 mL/min/1.73 m², p<0.0001) compared to subjects without MS. There was a significant graded increase in the prevalence of CKD with number of components of MS. The multivariate-adjusted odds ratio of CKD in subjects with MS compared with subjects without MS was 1.50 (95% CI, 1.19 to 1.90, p<0.0001). Compared with subjects with 0 or 1 components, subjects with 5 components of MS had multivariate-adjusted odds ratio of 6.58 (CL 4.07 to 7.74, p<0.0001).

**Conclusions:** Metabolic syndrome is a significant determinant of CKD in Korean general population. Prevalence of low HDL-cholesterol was higher compared to studies from the US and Japan with a variable prevalence of CKD.

**FP172 CLINICOPATHOLOGIC STUDY FOR ASYMPTOMATIC URINARY ABNORMALITIES**

Sung-Do Kim, Byoung-Soo Cho. Pediatrics, East West Kidney Diseases Research Institute, Seoul, South Korea

**Introduction and Aims:** Since 1998, by law, all school children in Korea must have an annual urinalysis. The first early morning urine specimen is examined by a simple dipstick method for the detection of proteinuria, hematuria and sugar. If a urine test is positive, a second test is performed by pediatric nephrologists. We analyzed the results of clinical data and the renal biopsy findings of patients detected by school urinalysis screening from 1998 to 2005.

**Methods:** We analyzed urinalysis data of 2,100 children referred for urinary abnormalities by school urinalysis screening. We also investigated histopathologic findings and diagnosis of 1,300 asymptomatic persistent and/or proteinuria patients who took renal biopsy.

**Results:** The male to female ratio was 1.4:1 and the mean age 9.8 years. The chief complaints for renal biopsy were 578 cases (45.3%) of isolated hematuria, 109 cases (8.5%) of isolated proteinuria and 479 cases (37.5%) of hematuria combined with proteinuria. In the histopathological findings, primary glomerular disease was 75.8% which was IgA nephropathy in 30.1%, mesangial proliferative glomerulonephritis in 27.2%. Systemic disease was 11.4% which was Henoch-Schonlein nephritis in 10.4%, and lupus nephritis in 0.8%. Alport syndrome showed 1.2% as a hereditary disease.

**Conclusions:** Early detection through school urinalysis screening and confirm diagnosis by renal biopsy seem to be helpful for assessment of prognosis and intervention of disease progression.

**FP174 GETTING THE MOST FROM NEPHROLOGY OUTPATIENTS: ΔGFR AN INTUITIVE METHOD OF ASSESSING PROGRESSION AND REGRESSION OF CHRONIC KIDNEY DISEASE (CKD)**

A. Raineys1, 2, M. Quinn3, K.J. Curns4, A.H. Marshall2, F. Kees2, G. Savage2, D. Fogarty1, 2Centre for Statistical and Operational Research (CenSSOR), The Queen’s University, Belfast, United Kingdom;

2Department of Public Health and Epidemiology, The Queen’s University, Belfast, United Kingdom;

4Department of Nephrology, The Queen’s University, Belfast, United Kingdom

**Introduction and Aims:** The number of patients receiving renal replacement therapy in the UK is rising rapidly, costing over 2% of the total NHS budget. The Renal Association have published referral guidelines for CKD re-emphasising the importance of assessing patients with progressive CKD at Nephrology outpatients. In the light of current guidelines our aim was to investigate if the assessment and referral of patients is appropriate based on the progressive risk of CKD.

**Methods:** In Northern Ireland 2,892,340 creatinine samples from 1st Jan 2001 - 31st Dec 2002 were extracted from regional laboratories. Merging
these to an enriched General Practice dataset produced a cohort of 75,434 subjects containing 307,663 results. To capture progression over the two-year period, a three-point assessment was devised. Progression and periods of regression were characterised by the gradients ΔA and ΔB. A cut-off level (eGFR 60mL/min) was additionally used to categorise the change in patient’s eGFR. Progression was also categorised as stable (<1mL/min/yr), slow (1-5mL/min/yr) and rapid (>5mL/min/yr).

Results: 56,356 (74.7%) subjects had “all eGFR results” >60 mL/min throughout the entire period. 11,249 (14.9%) had “all eGFR results” <60 mL/min and 5017 (6.7%) had a minimum eGFR measured below 60mL/min and yet subsequently had a value measured above 60mL/min. In total, 1,167 were known to Nephrology services. Of these, 341 (29.2%) had an eGFR>60mL/min over the two year period. Importantly, 2,699 (3.6%) subjects unknown to nephrology demonstrated a rapid decline from stage 1 or 2 CKD to stage 3 or worse.

Conclusions: Progression of CKD is often taught to be linear; this data indicates that alternative patterns of progression occur in the natural history of CKD, including improvement in function. Significant numbers of subjects attending Nephrology services have no evidence of progressive decline in eGFR whilst the vast majority with CKD remain unseen. Although some of these patients may have important reasons for attending Nephrology services, this may be to the detriment of those with more progressive CKD.

FP175 PREVALENCE OF RENAL DISEASE IN HEPATITIS C INFECTED PATIENTS

Gearoid McMahon 1, F.E. Murray 2, M. Fahy 2, J.J. Walsh 1. 1Dept of Nephrology, Beaumont Hospital, Dublin, Ireland; 2Dept of Hepatology, Beaumont Hospital, Dublin, Ireland

Introduction and Aims: The reported incidence and sequelae of Hepatitis C varies significantly internationally and extra-hepatic manifestations of the disease are common. However, despite the well recognised association between hepatitis C and glomerulonephritis, the prevalence of renal disease in this population has not been studied. The purpose of this prospective study was to determine the prevalence of and risk factors for renal disease in a Northern European population attending a specialist Hepatitis C clinic.

Methods: All patients attending the specialist hepatitis C clinic during a 3 month period provided urine and blood samples for renal and liver function, cryoglobulins, complement, anti-nuclear factor, rheumatoid factor and ANF. Renal disease was defined by the presence of significant proteinuria (>300mg/24hrs), abnormal urinalysis (x3) and/or a raised serum creatinine (>110mmol/l).

Results: 72 patients (41 male) were included in the study. 59 were HCV PCR positive and 13 were currently PCR negative. 46 patients had a history of intravenous drug use, 18 had received infected anti-D immunoglobulin and 8 were sporadic cases. Mean age was 49±10.9 years. 65% of patients were genotype 1 and 35% were genotype 3. Mean duration of infection was 13.7±9.5 years. 33% were ANF positive and 47% were RF positive. None of the patients had a history of diabetes mellitus or hypertension. 8 patients (11%) had evidence of renal disease, 7 patients had proteinuria and 1 had an abnormal urinalysis. All 8 patients were PCR positive. There was no difference in age, gender, duration of infection or aetiology between those with and without renal disease. There was a trend towards increased inflammation and fibrosis in the liver biopsies of those with renal disease.

Conclusions: These data indicate that renal disease is not uncommon in hepatitis C. Overall, 11% of the patients in this study had evidence of renal disease and 27% had cryoglobulinaemia. This represents a higher prevalence of renal disease in those with hepatitis C than in the general population. We suggest that all patients with hepatitis C, particularly those with cryoglobulinaemia, should be screened for renal disease as early recognition may allow appropriate treatment and possibly reduce future complications. Further studies are required to confirm these findings.

FP176 GENDER DIFFERENCE IN CKD-MBD AMONG PRE-DIALYSIS PATIENTS (OVIDS-CKD)

Naofuko Fujii 1, Takayuki Hamano 1, Satoshi Mikami 2, Yasuyuki Nagasawa 2, Yoshitaka Isaka 2, Takahito Ito 2, Enyu Imai 2, 1Nephrology, Hyogo Prefectural Hospital Nishinomiya, Nishinomiya, Hyogo, Japan; 2Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan

Introduction and Aims: We have reported the importance of gender difference in CKD-MBD among hemodialysis patients. CKD-MBD is characterized by three abnormalities; laboratory abnormalities, bone abnormalities, and calcification of vasculature. Male gender is associated with the severer calcification both in hemodialysis and pre-dialysis patients. But little is known about the gender difference in pre-dialysis CKD patients. Our aim is to elucidate the effect of gender on laboratory and bone abnormalities.

Methods: We conducted a cross-sectional observational study in CKD patients (OVIDS-CKD; Osaka Vitamin D Study in CKD), who had not received or were not receiving glucocorticoid, bisphosphonates, or active vitamin D. Pre-menopausal females were excluded. Whole PTH (wPTH), bone specific alkaline phosphatase (BSAP), adjusted calcium (Ca), phosphorus (P), 25-hydroxyvitamin D (25-OHD), and estradiol (E2) were measured.

We studied the interaction of gender with the relationship between laboratory parameters and estimated glomerular filtration rate (eGFR). We also measured bone mineral density (BMD) in lumbar spine and femoral neck by dual X-ray absorptionmetry. Multiple linear regression analysis for BMD T-score was performed to determine the significant contributors.

Results: We enrolled 249 patients (186 males, mean age 60.7 years, eGFR 45.8 23.2 mL/min/1.73m²). P was significantly higher in female, but no difference was observed in Ca between genders. E2, which elevated with the reduction of eGFR in both sexes, was significantly higher in male throughout CKD stages. Whole PTH increased as renal function declined without significant difference between genders. However, BSAP was statistically higher in female. Thus, BSAP/wPTH, which denotes skeletal sensitivity to PTH, was significantly higher in female at eGFR ≥30. But at the lower eGFR, there was no difference between genders (Fig. 1). Multiple linear regression analyses revealed that the significant positive contributors to higher lumbar T-score were E2, BMI, and 25-OHD, whereas in femoral neck 25-OHD, E2, BMI, and eGFR were the positive contributors. BSAP was negatively associated with both lumbar and femoral neck T-scores.

Conclusions: Females seemed to have higher sensitivity of the bone to PTH than males at eGFR ≥30, although the effect of uremia might override the gender effect at eGFR <30. The higher E2 levels in males and the positive correlations between E2 and BMD implied protective effect of E2 on bone metabolism. We should pay attention to gender difference in the management of CKD-MBD in pre-dialysis patients.
FP177 ★ CLINICAL CHARACTERISTICS OF THE POPULATION FROM THE CROATIAN FOCUS OF ENDEMIC NEPHROPATHY
Jelena Kosi1,4, Marica Miletic Medved2,6, Dubravka Cvorsic1,4, Jadranka Sertic1,4, Anamarija Kovac Pete1,4, Ivan Pecim1,4, Zvezka Dika1,4, Duško Kuzmic1,4, Bojan Jelakovic1,4,1 University Hospital Center Zagreb, Zagreb, Croatia; 2 Institute for Public Health Brodsko-Posavska County, Slavonski Brod, Croatia; 3 General Hospital “Dr Josip Bencevic”, Slavonski Brod, Croatia; 4 Croatian Center for Endemic Nephropathy, Slavonski Brod, Croatia.

Introduction and Aims: The aim of this study was to establish clinical and laboratory characteristics of the population living in the Croatian region of endemic nephropathy (EN).

Methods: This study included 738 individuals from EN villages (307 male (M), 431 female (F)), and 120 subjects from a control village (K) (50 M, 70 F). No differences in the distribution of gender and age were observed between EN and K (p<0.01). Following administration of a detailed questionnaire and clinical examination, investigators obtained blood and urine samples from the subjects. The population was classified according to WHO criteria as diseased (D), suspect (S), at risk (R) and others (O). The following definitions were used: microalbuminuria (MA) > 30 mg/g; alpha-1-microalbuminuria (alpha-1) > 20 mg/g; hypertension, BP > 140/90 mmHg and/or antihypertensive drug therapy; and anemia (AN) as Hb < 120 g/l in M and <113 g/l in F. Renal disease (RD) was classified according to NKF classification.

Results: The frequency of the WHO categories in this group was: D=1.4% (M, 1.73% vs. F, 1.34%, respectively), S=5.6% (M, 7.79% vs. F, 4.83%). If we analyze only the portion of population who resided > 20 years in an EN village, then the incidence of D is 1.8% and S is 6.8%. In the subgroup of persons living in EN villages < 10 years, there was none in the D group and only 2% were in the S category. In the EN villages, we found an increased MA frequency compared with K (20.0% vs. 9.8% M, respectively; 16.6% vs. 9.37% F, respectively), as well as an increased frequency of alpha-1 (21.73% vs. 13.72% M, respectively; F 9.48% vs. 4.54%, respectively). No similar differences were observed between subgroup O and K. The prevalence of hypertension was slightly lower in EN villages than in K (51.75% vs. 58.9%; M 54.0% vs. 57.1%; F 51.97% vs. 58.46%, respectively). There were no differences in the frequency of RD stages > 2 (by NKF classifications) or in anemia between EN and K. The duration of residence in EN villages was significantly correlated to MA, alpha-1 and serum creatinine, but was not significant for those living < 20 years in EN area and in residents. A significant correlation was observed between years living in an EN area and the presence of MA, alpha-1 and serum creatinine even in persons in WHO categories R and O.

Conclusions: The incidence of D and S in this group has remained the same as before. The duration of residence in the endemic area affects EN prevalence. The two village populations differed in MA, alpha-1, and hypertension frequency but not in anemia and renal disease stage > 2. The known significant association between early renal impairment in persons classified as R and O living in EN villages, indicates that new diagnoses of S and D will be registered in the next several years regardless of whether the causative agent is still present or active.

FP178 ★ PREDICTORS OF GLOMERULAR FILTRATION RATE IN CONGESTIVE HEART FAILURE – THE NORWEGIAN EXPERIENCE
Bard Waldum1, Arne Westheim2, Morten Grundtvig3, Lars Gullesstad4, Torstein Hole5, Ingrid Ols1,1 Department of Nephrology, Ulleval University Hospital, Oslo, Norway; 2 Department of Cardiology, Ulleval University Hospital, Oslo, Norway.

Introduction and Aims: Renal dysfunction is common in patients with congestive heart failure (CHF) and is associated with an adverse prognosis. The aim of this study was to determine predictors of glomerular filtration rate (GFR) in a Norwegian cohort with congestive heart failure.

Methods: The registry contains data from 26 heart failure out-patient clinics at regional hospitals. Patients with heart failure NYHA class I-IV were consecutively included at the first contact. For this analysis only patients with systolic dysfunction with ejection fraction (EF) < 45% were included, and baseline data from 2665 patients (age 69±11.9 years, 25.6% females) with CHF (NYHA class I: 4.5%, II: 41.9%, IIIA: 39.8%, IIIB: 12.3%, IV: 1.6%) were used. GFR was determined with the mMDRD formula, and classified accordingly in stages 1-5 of chronic kidney disease (CKD). In multiple regression analysis with GFR as the dependent variable, age, sex, ejection fraction (EF), NYHA class, systolic blood pressure (SBP), use of ACE inhibitor/ARB and body mass index (BMI) were entered as independent variables.

Results: Mean EF was 29±8% in this cohort. Average GFR was 65.4±23.1 ml/min. The prevalence of GFR < 60 ml/min was 44.7%, 13.7% had CKD stage 1, 43.1% stage 2, 37.8% stage 3, 4.7% stage 4, 0.6% had CKD stage 5. The use of ACE inhibitors (79%) and angiotensin II receptor antagonist ARB (27%) was prevalent, and close to 20% used combination of the two drugs. 14% used neither ACE inhibitor or ARB. Multiple regression analysis revealed that all entered variables except EF (p=0.157) were independently and significantly related to GFR, age (p<0.001), gender (p<0.001), SBP (p<0.001), NYHA class (p<0.001), BMI (p<0.001), use of ACE inhibitor/ARB (p=0.002). Among subjects below 60 years only age came out as an independent predictor (p=0.001), while gender did not reach statistical significance (p=0.09). While in subjects > 60 years of age (n=1792), age and gender remained independent predictors as did BMI, NYHA class and SBP while EF and use of ACE inhibitors and/or ARB did not reach statistical significance as independent predictors (p=0.053 and 0.082, respectively).

Conclusions: In this population with systolic dysfunction and CHF and with EF < 45%, renal dysfunction was prevalent with 44% had GFR below 60 ml/min. A total of 86% used ACE inhibitors and/or ARB, and this was associated with higher GFR. Age and gender were the strongest independent predictors of GFR. In this cohort, EF was not an independent predictor in contrast to NYHA class, SBP and BMI.

FP179 CHRONIC KIDNEY DISEASE IN PRIMARY CARE SETTINGS IN SPAIN. THE EROCAP STUDY
Alberto Martinez-Castelao, Aleix Cases, Angel L.M. De Francisco, Juan Jose De La Cruz, Mariano De La Aliguera, Isabel Egocheaga, Jose Luis Goriz, Jose Luis Listerri, Rafael Marin, Nephrology, H.U.Belvitge, Hospitalit, Barcelona, Spain; Nephrology, H Clinic, Barcelona, Spain; Nephrology, HU Marqués Valdecilla, Santander, Cantabria, Spain; Med Preventiva, Faculty of Medicine, Madrid, Spain; Primary Care, CAP La Mina, Barcelona, Spain; Primary Care, CAP Onda de Oro, Madrid, Spain; Nephrology, HU Dr Peset, Valencia, Spain; Primary Care, CAP Alacuar, Valencia, Spain; Nephrology, HUCA, Oviedo, Spain.

Introduction and Aims: This cross-sectional, multicenter study investigated the prevalence of chronic kidney disease (CKD) and associated disorders, in an adult population sample (>18 years old) attending Primary Care services in Spain.

Methods: Estimated glomerular filtration rate (Modification of Diet in Renal Disease equation) was used for analysis of CKD prevalence according to NFK-KDOQI stages.

Results: Serum creatinine and other laboratory parameters, blood pressure and medical history of cardiovascular risk factors or disease (hypertension, dyslipidemia, diabetes, congestive heart failure, coronary artery disease, stroke or peripheral vascular disease) were obtained in 7202 patients attending Primary Care Centers. 47.3% were males, mean age 60.6±14.3 years, BMI 28.2±5.3 kg/m2, 27.6% were overweight (27-30 kg/m2) and 32.1% obese (BMI >30kg/m2). The prevalence of cardiovascular (CV) risks factors (RF) were: absence in 17.3%, one factor 26.9% two 31.2%, and 23.6% presented ≥3. The frequency of CVRF was hypertension (66.7%), dyslipidemia (48%) and diabetes (31.5%). Congestive heart failure, coronary artery disease, stroke or peripheral vascular disease prevalence was lower than 10%. The prevalence of eGFR <60 ml/min/1.73 m2 was: stage 3 (GFR 60-30 ml/min) 19.7%; stage 4 (GFR 30-15 ml/min) 1.2%; stage 5 no dialysis (GFR <15 ml/min) 0.4%. This prevalence increased with age in both sexes and 33.7% of patients attending Primary Care services over 70 years presented an eGFR < 60 ml/min. Of the total number of patients having an eGFR < 60 ml/min 37.3% had serum creatinine levels within the normal range.

Conclusions: This study documented the substantial prevalence of significantly abnormal renal function among patients attended at the Primary Care.
CAN A PHYSIOTHERAPY-LED OUTPATIENT RENAL REHABILITATION PROGRAMME ACHIEVE SIGNIFICANT IMPROVEMENTS IN EXERCISE CAPACITY, FUNCTIONAL ABILITY AND QUALITY OF LIFE IN PATIENTS WITH CHRONIC KIDNEY DISEASE (CKD)

Sharlene Cook, Herolin Hopwood. Physiotherapy, King’s College Hospital, London, United Kingdom

Introduction and Aims: The majority of patients can exercise during all stages of chronic kidney disease (CKD) but exercise is still not routinely advocated in renal disease compared with best practice in other diseased populations such as cardiac and pulmonary disease. The first U.K physiotherapy-led Renal Rehabilitation Programme, comprising of 12 weeks of twice-weekly supervised exercise and education sessions, and once-weekly specific home exercises, was initiated to determine whether patients with CKD could achieve significant improvements in exercise capacity and functional ability.

Methods: 30 patients (13M,17F) have completed 12 weeks in the programme and have been monitored for exercise performance tests at baseline and 12 weeks. Performance exercise tests included the Incremental Shuttle Walk Test (ISWT), sit to stand 60 (TUAG3m), stair climb/descent (SCD), Duke’s activity status index (DASI) and the Hospital Anxiety Depression assessment (HAD).

Results: Student’s paired t-test analyses were performed to assess differences between baseline and 12 week data. ISWT improved by 54% (p<0.001), TUAG3m by 28% (p<0.001), SCD by 35% (p<0.001), DASI by 67% (p<0.001), HAD anxiety score by 11% (p<0.001) and HAD depression score by 27% (p<0.001) after 12 weeks.

Conclusions: Increased fitness and muscle strength makes activities of daily living easier as is demonstrated by the significant improvements in the DASI score, and enables some people to increase return to activities that they enjoy such as walking or playing sport. Preliminary experience from this renal rehabilitation programme combining 12 weeks of exercise and education suggests that significant improvements in exercise capacity and physical functioning can be achieved in CKD patients with a supervised outpatient exercise programme.

SHORT TERM SURVIVAL IN CHRONIC KIDNEY DISEASE PATIENTS WITH STROKE

Adalbert Schlaffer 1, Nicoleta Genovea Mardare 2, Adrian Covic 2, Ligia Petrica 1, Maxim Petrica 1, Adelina Mihaescu 1, Norica Posta 1.
1Nephrology Department, Emergency Clinical Hospital, Timisoara, Romania; 2Dialysis and Transplantation Center, „C.I. Parhon” University Hospital, Iasi, Romania; 3Neurology Department, Emergency Clinical Hospital, Timisoara, Romania

Introduction and Aims: Chronic kidney disease (CKD) occurs commonly in patients with vascular disease. In addition, CKD is a risk factor for the development and progression of vascular disease. Recent studies have confirmed that even early CKD constitutes a significant risk factor for non-fatal cardiovascular events and death. Our aim was first to investigate in a large series of consecutive patients hospitalized for stroke the prevalence of CKD and second to assess determinants short-term survival, in this high risk population with associated cardiovascular disease and CKD.

Methods: Study population: 1090 consecutive subjects (mean age was 66.6±11.5 years, 40.3% males) admitted for confirmed (by CT scan) ischemic or hemorrhagic stroke. Collected data: associated comorbidities, cause of CKD, biochemical parameters at admission including serum creatinine, development of acute renal failure during hospitalization (as defined by RIFLE criteria) and 30 days survival.

Results: The demographic characteristics of the study group are presented in Table 1. There were no significant differences in biochemical parameters between the four CKD subgroups, at baseline. In this cohort, 187 patients died during the first 30 days after stroke.

The deceased patients were older, had higher serum creatinine at admission and higher serum glucose (p<0.05). The mean survival in CKD stage 4 and 5 patients was 16±2 days, significantly worse than for other CKD stages (log rank test = 0.0001). Cox Regression model show age (RR = 1.037, 95% CI = 1.021-1.054), serum glucose (RR = 1.005, 95% CI = 1.002-1.007), CKD stage4 and 5 (RR = 2.563, 95% CI = 1.489-4.409), presence of chronic heart failure (RR = 0.418, 95% CI = 0.30-5.83), type of stroke (RR = 2.59, 95% CI = 1.87-3.67) and development of acute renal failure (RR = 0.326, 95% CI = 0.22-0.483) to be predictors of 30 day survival.

Conclusions: A chronically impaired renal function is frequently encountered in patients admitted with stroke and has severe impact on short-term mortality and morbidity.
THE EVALUATION OF EFFECTS OF L-CARNITINE SUPPLEMENTATION ON PREVENTION OF MUSCULAR SYMPTOMS IN PATIENTS UNDER CHRONIC HEMODIALYSIS

Jamshid Roozbeh, Hamed Jalaeian, Department of Internal Medicine, Nephrology, Nemazi Hospital, Shiraz; University of Medical Sciences, Shiraz, Iran; Shiraz Organ Transplant Center, Nemazi Hospital, Shiraz; University of Medical Sciences, Shiraz, Iran

Introduction and Aims: L-carnitine plays an important role in oxidation of fatty acids. It is essential in tissues that preferentially use fatty acids for their energy needs, especially skeletal muscle and myocardium. It is lost from plasma during hemodialysis and is lower in skeletal muscle of end-stage renal disease (ESRD) patients undergoing chronic hemodialysis. The aim of study was to evaluate effects of L-carnitine supplementation on prevention of muscular symptoms in patients under chronic hemodialysis.

Methods: In a double-blind clinical trial, sixty ESRD patients were assigned to two groups: Group A consisted of 30 patients who received 500 mg oral L-carnitine everyday for 8 weeks, and group B received a placebo. At 2, 4, and 8 weeks after the initiation of treatment, subjects were asked about muscle symptoms (weakness, fatigue, cramps/aches).

Results: 93.2% of subjects of group A had at least some improvement in muscular symptoms. Five patients (16.6%) reported mild progress, 11 (36.6%) had moderate and 12 (40%) reported marked improvement. Whereas, only nine subjects (30%) reported some mild improved muscular symptoms and the rest (70%) did not report any improvement. (p<0.05).

Conclusions: Low-dose L-carnitine supplementation in hemodialysis patients improves muscular symptoms and their sense of wellbeing by restoring carnitine tissue levels and washing out cumulative acyl moieties.

BONE MARROW IRON STORES AND IV IRON SUPPLEMENTATION IN ANEMIA OF NON-DIALYZED CKD PATIENTS

Gabriel Mircescu, Simona Stancu, Adrian Zagravu, Ligia Petrescu, Liliana Ganeza, Cristina Capusa, Mircea Coman, Ana Stancu, Nephrology, Carol Davila Clinical Hospital of Nephrology, Bucharest, Romania

Introduction and Aims: Iron deficiency is common in anemic CKD nondialyzed patients. By it’s correction only, about 1/3 of patients reached the hemoglobin (Hb) target. Peripheral markers of iron deficiency are not validated yet and central markers (eg bone marrow iron stores) are seldom reported.

This study aims to evaluate the relation among the bone marrow iron stores, peripheral markers of iron deficiency and therapeutic effect of IV iron sucrone in anemic CKD non-dialyzed patients.

Methods: 70 anemic (Hb<10.5g/dL) CKD patients EPO and iron-naive were enrolled [55% men; median age 60 (24-84)ys]. The main primary renal diseases were vascular and glomerular nephropathies (43% and 33%); only 11% had diabetic nephropathy. The mean eGFR (MDRD) was 9.6mL/min (64% CKD stage 5). 40% had CRP >0.4g/dL, 57 subjects died. Median follow up was 1.6 years. Serum albumin at commencement of RRT was measured by Davies index. Serum transferrin saturation (TS), serum ferritin parameters of iron status were evaluated at baseline. The percentual distributions of patients according to bone marrow iron stores (absent, normal, high) in quartiles of serum iron, TS and serum ferritin were evaluated. One month after therapy (iron sucrose - VENOFER® - 200mg IV push in 2-5min, daily for 5 days), Hb and peripheral parameters of iron deficiency were iron serum (mcg/L)*

Results:

- Serum iron (mcg/L)*
  - A: 50 (17.91) (1)
  - B: 75 (45.16) (2)
  - C: 78 (37.120) (3)

- TS (%)
  - A: 21.6 (7.5) (1)
  - B: 26.7 (8.2) (2)
  - C: 31.8 (7.3) (3)

- Serum ferritin (mcg/L)*
  - A: 125 (39-510) (1)
  - B: 209 (56-450) (2)
  - C: 357 (113-727) (3)

- After iron therapy
  - Hb (g/dL, mean±SD)
    - A: 10.0 (±0.9) (1)
    - B: 10.4 (±0.9) (2)
    - C: 9.3 (±0.9) (3)
  - ΔHb (g/dL, mean±SD)
    - A: 1.1 (±0.3) (1)
    - B: 1.0 (±0.19) (2)
    - C: 0.8 (±0.4) (3)

*median, iq range; (1) p = 0.05; A vs B; (2) p < 0.05; B vs C; (3) p < 0.05; A vs C

Conclusions: Although iron stores, ferritin level and TS seem to be useful indicators of absolute iron deficiency, predicting the increase in Hb after correction, the therapeutic trial of iron supplementation is worthy in anemic pre-dialysis CKD patients as even those with repleted iron stores could respond to IV iron.

A PROSPECTIVE COHORT STUDY OF SURVIVAL IN INCIDENT ADULTS WITH END STAGE KIDNEY DISEASE, RESIDENT IN SOUTH WEST IRELAND

Gemma M. Browne, William D. Plant, Department of Renal Medicine, Cork University Hospital, Cork, Ireland; Department of Epidemiology and Public Health, University College Cork, Cork, Ireland

Introduction and Aims: In the Republic of Ireland there is currently no registry of end stage kidney disease (ESKD). This study prospectively follows the cohort resident in counties Cork and Kerry (population 580,356) commencing renal replacement therapy (RRT) from 01.01.2002 to 31.12.2005. Survival and the factors that predict survival were modelled. UK Renal Registry data were used for comparison.

Methods: 197 adult subjects commenced RRT. Covariates include: age at start RRT ESKD aetiology, mode of RRT, initial type of dialysis access and nephrology review for at least 3 months prior to RRT. Co-morbidity was measured by Davies index. Serum albumin at commencement of RRT was recorded. Survival time was from commencement of RRT to 1.Jan.2006 or death, without censure at transplant. Cox regression was used to test potential factors influencing survival and to derive crude and adjusted hazard ratios (HR). Bidirectional stepwise model regression excluded covariates no longer associated with survival. Crude mortality rate was calculated. 1 year cohort survival was compared to the UK Renal Registry Report 2004.

Results: The crude mortality rate was 16.2 deaths per 100 person-years (95% CI 12.5, 21.0). 57 subjects died. Median follow up was 1.6 years (IQR 0.7, 2.8). Haemodialysis was the first modality in 162 (83%) patients, and 34 (17%) commenced RRT with CAPD, with 1 pre-emptive transplant. Age, ESKD aetiology, mode of RRT and albumin<30g/L had crude effects, but were no longer associated with survival in the multivariable model.

FP186 Atherosclerotic Renovascular Disease (ARVD) in a High Cardiovascular (CV) Risk Population

Carmelita Marcantoni 1, Luca Zanoli 2, Stefania Rastelli 2, Giovanni Tripoli 3, Salvo Virzi 4, Domenico Di Landro 1, Corrado Tamburino 4, Carmine Zoccali 5, Pietro Castellino 2, 1Nephrology, Cammizzaro Hospital, Catania, CT, Italy; 2Internal Medicine and Nephrol, University of Catania, Catania, CT, Italy; 3CNR-IBIM, Reggio Calabria, RC, Italy; 4Cardiology, University of Catania, Catania, CT, Italy

Introduction and Aims: ARVD may play a role in the pathophysiology and progression of cardiovascular heart failure and chronic renal failure. Few studies have addressed renal artery stenosis (RAS) prevalence in populations with very-high renal CV risk, such as patients (pts) undergoing diagnostic or therapeutic cardiac catheterization.

This study was performed to determine the prevalence of ARVD in a cohort of patients with high renal CV risk, referred for diagnostic or therapeutic cardiac catheterization.

Methods: From April 2006, all consecutive pts undergoing cardiac catheterization (acute MI excluded) at a single institution were also evaluated for the presence of RAS by renal angiography. Clinical, laboratory, and angiographic data were recorded. Pts enrollment will end by April 2007.

Results: Renal arteriography was performed in 967 pts. Angiographically evident ARVD was present in 252 pts (26.1%), with RAS ≥50% in 62 pts (6.4%) and <50% in 190 pts (19.6%); monolateral in 74.6% of pts. Demographic data are reported in the table. Coronary artery disease (CAD) was more severe in pts with significant RAS than in pts without ARVD, showing a significant higher prevalence of the three vessel disease (43.3% vs 20.2% P<0.001). All patients with significant RAS had at least a single vessel-CAD with 73.3% of them with 2- or 3-vessel CAD.

There were no complications related to renal artery disease screening.

Conclusions: The prevalence of renal artery stenosis >50% in an unselected cohort of pts undergoing cardiac catheterization was significant (6.5%). Our data support the role of renal arteriography in order to detect clinically silent ARVD during cardiac catheterization in patients with high renal CV risk.

Furthermore, some clinical factors (older age, mild impaired renal function, blood pressure control, hyperlipidemia, coronary and peripheral atherosclerotic vascular disease) seem to be associated with severity of atherosclerotic renovascular disease.

Epidemiology of CKD I

Hon-yen Wu 1,2, Chih-Kang Chang 1, Chung-Jen Yen 1, Kuan-Dun Wu 1
1 Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan; 2Department of Internal Medicine, Far Eastern Memorial Hospital, Taipei, Taiwan

Introduction and Aims: Uric acid has been considered as a non-traditional risk factor of cardiovascular disease (CVD). Chronic kidney disease (CKD) patients have a high risk of CVD-related morbidity and mortality. Epidemiological evidences for the significance of hyperuricemia on the risk for kidney dysfunction is scarce, especially in the geriatric population. We hope to identify the possible relationship between hyperuricemia and renal function in the elderly population.

Methods: All patients were older than 65 years visiting National Taiwan University Hospital for elderly health examination during Jan. and Dec. 2003. We applied the Modification of Diet in Renal Disease (MDRD) equation 7 to estimate glomerular filtration rates (GFRs). Sex, age, body height, and body weight were recorded. All biochemistry data were measured in a single clinical laboratory. Linear regression model was applied to find factors that are independently associated with GFRs. Receiver operating characteristic (ROC) curve identify the cut-off values to predict advanced CKD (stage III-V).

Results: The study enrolled 491 men and 309 women with mean age (74.5±5.2), mean uric acid (6.2±1.5 mg/dL) and GFRs (87.8±18.5 ml/min/1.73m2). Age, serum uric acid, creatinine and BUN are negatively correlated with MDRD-GFRs, but serum albumin and hemoglobin are associated positively. Stepwise regression identifies seven factors as an independent predictor for MDRD-GFRs (Table 1). Hyperuricemia acts as an independent predictor for GFRs after adjusting conventional factors influence renal function.

ROC curves identify uric acid greater than 6.75 mg/dL in men, and 5.95 mg/dL in women were the cut-off value to predict advanced CKD in the geriatric population (Figure 1).

Predictive variables Multivariate regression coefficients (B) Regression full model = 0.615 95% CI for B value
| Serum creatinine, mg/dl | -22.170 | -24.632 to -19.708 | <0.001 |
| Serum blood urea nitrogen, mg/dl | -0.832 | -1.016 to -0.659 | <0.001 |
| Male, vs. female | 7.452 | 5.348 to 9.555 | <0.001 |
| Age, per year-old | -0.555 | -0.712 to -0.397 | <0.001 |
| Serum uric acid, mg/dl | -1.657 | -2.220 to -1.094 | <0.001 |
| Serum albumin, g/dl | 6.146 | 2.854 to 9.437 | <0.001 |
| Serum total cholesterol, mg/dl | -0.029 | -0.054 to -0.004 | 0.023 |

Fig. 1. Receiver operating characteristic (ROC) curve analysis of serum uric acid levels for the prediction of advanced chronic kidney disease (CKD) in geriatric (A) male population. Cut-off value of serum uric acid ≥7.55 mg/dL, sensitivity, 69.2%, specificity, 56.6; and area under curve, 0.713 (95% Confidence interval, 0.609-0.816). (B) Female population. Cut-off value of serum uric acid ≥5.95 mg/dL, sensitivity, 50.0, specificity, 64.7, and area under curve, 0.671 (95% Confidence Interval, 0.545-0.795).

Conclusions: Hyperuricemia were independently associated with poor GFRs in the geriatric population. Whether hypouricemic therapy leads to renal protection in this CKD high risk population deserves further investigation.
Introduction and Aims: Several studies investigated the factors related to the chronic dialysis (CD) modality choice and the outcomes of patients starting with hemodialysis (HD), hemodiafiltration (HDF) and peritoneal dialysis (DP). However, few studies were performed using data derived from an area-based registry. The aim of the study is to evaluate the factors influencing the CD modality choice and the effect of the first type of dialysis on patients’ survival.

Methods: Prospective cohort study of 8122 undergoing chronic dialysis patients notified to Lazio Dialysis Registry (Italy) from 1-1-1995 to 31-12-2005. We performed a multimodal logistic regression to estimate determinants of initial modality of CD, and a multiple Cox model to estimate mortality hazard ratios (HR).

Results: We observed 90.4% HD, 2.2% HDF, 7.3% DP as first dialysis modality; an older mean age in HD patients (64.2, SD 15.8), compared to HDF (55.6, SD 17.4) and DP (58.5, SD 18.6). A higher probability of initiation with HD compared both HDF and DP was found for: age >64 years (OR 3.50; 95%CI 2.40-5.11 and OR 1.52; 95%CI 1.25-1.85), cancer (OR 2.59; 95%CI 0.94-7.13 and OR 1.88; 95%CI 1.17-3.04). A higher probability of initiation with HD compared to DP was found for vascularopathy (OR 1.40; 95%CI 1.04-1.88) and compared to HDF for women (OR 1.68; 95%CI 1.17-2.43). A higher probability of initiation with HDF compared to HD was found for coronary heart disease (OR 1.54; 95%CI 1.02-2.33) and congestive heart failure (OR 1.71; 95%CI 1.03-2.84) and compared to DP for HCV positive subjects (OR 2.16; 95%CI 1.14-4.09). A higher probability of initiation with DP compared both HD and HDF was found for patients with self-sufficiency (OR 2.12; 95%CI 1.67-2.69 and OR 2.09; 95%CI 1.33-3.29). A higher probability of initiation with DP compared to HD was found for coronary heart disease (OR 1.36; 95%CI 1.06-1.73) and hypertension (OR 1.47; 95%CI 1.22-1.76) and compared to HDF for women (OR 1.85; 95%CI 1.24-2.77) and age >64 years (OR 2.30; 95%CI 1.52-3.49). No difference in survival was found between patients starting with HD or HDF (HR 1.04; 95%CI 0.78-1.38) and DP (HR 1.10; 95%CI 0.94-1.29).

Conclusions: Our findings seems to suggest that evaluation of clinical condition and patient’s autonomy are determinants of choice of initial modality of CD treatment. However, as we confirm no association between long-term survival and first dialysis modality, the preference of the patients should have more relevance in the choice of first type of CD treatment.
Results: Patients receiving low protein diet spent on average 21.7 months in "pre-dialysis", 1.9 months in "pre-dialysis", and 0.4 months as "pre-dialysis". The corresponding figures for patients receiving normal diet were 20.1, 3.3 and 0.6 months, respectively. The excess time of 1.4 month in pre-dialysis together with the reduced mortality resulted in 0.022 more QALYs (equivalent to 1.1 more weeks in full health) compared to patients on normal diet. The total average two-year cost for a patient receiving normal diets and low protein diet amounted to SEK 193 655 and 132 698, respectively. Hence the cost saving of low protein diet per patient amounted to SEK 60 687.

Conclusions: Low protein diet could be favourable not only for patients in terms of less time spent with dialysis and a better quality of life but also in terms of costs saved for the health care sector.

**FP192**

**PROGRESSION OF CORONARY ARTERY CALCIFICATION IN PATIENTS WITH CHRONIC KIDNEY DISEASE. ROLE OF PHOSPHORUS BINDERS**

Domenico Russo, Yuri Battaglia, Elisa Buonanno, Ida Miranda, Carolina Ruocco, Luigi Russo, Anna Scafarto, Vittorio E. Andreucci. Department of Nephrology, University of Naples “Federico II”, Naples, Italy

Introduction and Aims: Coronary artery calcifications (CAC) are more frequent in patients on dialysis (ESRD-patients) than in general population and rapidly proceed. Progression may cause further cardiovascular events. Greater prevalence and progression of CAC have been ascribed to exogenous calcium load consequent to high-calcium dialysate, and/or calcium containing phosphate binders (CCPB). Prevalence and progression of CAC have been recently reported to be greater in pre-dialysis patients than in normal subjects; progression was found to be correlated to phosphorus despite the majority of patients had normal concentration; fatal and not-fatal cardiovascular events occurred with manifest progression of CAC.

In ESRD-patients progression of CAC can be halted by a non-calcium containing phosphate binder (sevelamer, S) but not CCPB. The present study was performed to assess the role of CCPB and S on the progression of CAC in patients with CKD not on dialysis (CKD-patients).

Methods: Consecutive out-patients (stage 3-4 CKD), homogeneous for age, biochemical variables and baseline TCS (mean TCS:320-470 Agaston Units) were randomized to receive S (1600 mg/day) or CCPB (calcium carbonate, 2 gr/day) throughout the study (18 months). In prior study these doses did not cause suppression of PTH and/or hypercalcaemia. Treated patients exhibiting hypercalcaemia or suppression of PTH exit the study. Agents affecting mineral metabolism were not allowed. Serum calcium, phosphorus, i-PTH, homocysteine, C-reactive protein, triglycerides, total cholesterol, high- and low-density lipoprotein cholesterol were measured every 3 months. Progression of CAC was assessed measuring total calcium score (TCS) by computed tomography. Scans were obtained at start (initial) and end of observation period (final). Data of patients treated with CCPB and S were compared with those of non-treated CKD-patients (Controls; C).

Results: Seventy-six patients were enrolled in three groups: C=n.27; CCPB=n.22; S=n.27. Initial and final biochemical variables were unchanged but final TCS was significantly increased in three groups. TCS proceeded by 56% and 55% in patients treated with C and CCPB, respectively; and by 21% in those treated with S.

Mean TCS and annualized progression were not different between patients treated with CCPB and C. No episodes of hypercalcaemia were encountered. PTH remained unchanged. Patients free from CAC at the start remained non-calculated at the end of the study.

Conclusions: Progression of CAC is rapid in CKD-patients despite baseline normality of mineral metabolism parameters and not exogenous calcium load. Progression was greater in patients treated with CCPB and C but small in those treated with S. Study design and small number of patients did not allow to determine in which manner S contributed to the benefit on CAC progression. When prescription and reimbursement problem will be overcome, larger studies are mandatory to better establish the efficacy of S in reducing CAC progression and eventually morbidity and mortality in CKD-patients.

**FP193**

**PREVALENCE OF HIV INFECTION IN DIALYSIS CENTRES IN SPAIN: PRELIMINARY RESULTS OF A SPANISH SURVEY (YEAR 2006)**

Nephrology Service, La Princesa University Hospital, Madrid, Spain; 2 Infectious Diseases Service, Hospital Clinic-IDIBAPS, Barcelona, Spain; 3 Renal Transplant Unit, Hospital Clinic-IDIBAPS, Barcelona, Spain; 4 Nephrology Service, Hospital Clinic-IDIBAPS, Barcelona, Spain; 5 Nephrology Service, Hospital Ramon y Cajal, Madrid, Spain; 6 Nephrology Service, La Paz University Hospital, Madrid, Spain; 7 Nephrology Service, Puerta del Mar University Hospital, Cadiz, Spain; 8 Nephrology Service, Hospital General de Elche, Elche, Spain; 9 Nephrology Service, Hospital de Cruces, Baracalda, Spain; 10 Nephrology Service, Hospital de Donostia, San Sebastian, Spain; 11 Nephrology Service, Bellvitge University Hospital, Barcelona, Spain

Introduction and Aims: The prognosis of HIV infection has improved with the widespread use of HAART. The aim of this study was to know the prevalence of HIV infection in Spanish dialysis patients and the clinical profile of the potential candidates for renal transplantation.

Methods: Prospective Spanish survey performed during the second trimester of 2006 using a standardized questionnaire to know the prevalence and characteristics of HIV infection in dialysis patients in Spain.

Results: 177 (48%) Spanish Dialysis centres have answered the ongoing survey. 28 centres have HIV infected patients (15.8%). There were 12899 patients included in dialysis programs: 11866 in hemodialysis (HD), 1017 in peritoneal dialysis (PD) and 16 in home-HD. HIV prevalence was 0.48% (63 HIV positive patients). Prevalence in HD, PD and home-dialysis programs was 0.42%, 1.2% and 0% respectively. The 63 HIV-infected patients under dialysis (50 in HD and 13 in PD) were analysed. Mean (range) age was 46 (29-73) years. 66% of cases were males. HIV risk factors were: parenteral HIV exposure in 51% (former drug abuse 93%; blood transfusions and others 7%); high risk sexual behaviour in 30% (heterosexuality 58% and homosexuality 42%), multiple risk factors in 4.7% and unknown in 14.3%. Mean (range) time from HIV infection was 11.5 (1-26) years and time on dialysis was 4.9 (1-26) years. The most frequent aetiology of end-stage renal disease were glomerulonephritis (35%) followed by diabetes mellitus (15%). 25% of the diagnosis were proven by biopsy. Nine patients (14%) were in renal transplant waiting list. 43% of the patients had previous AIDS defining events and 85% were under HAART regimens. The median (range)
CD4 T-cell count was 335 cells/mm³ (16-845). 77% had undetectable viral load. 64% and 54% of patients have coinfections with hepatitis C and B viruses, respectively. 29% of patients have diabetes mellitus and 27% had previous cardiovascular events.

**Conclusions:** HIV seroprevalence in Spanish dialysis patients is 0.48%, being higher in PD than in HD. There are a high percentage of patients with hepatitis C coinfection, diabetes mellitus and previous cardiovascular complications. Most of the patients are in an immunological and virological good situation and under HAART regimens. Some patients are in the renal transplant waiting list.

**FP194**  RELATIONSHIP BETWEEN VITAMIN D STATUS, PARATHYROID HORMONE LEVELS AND BONE MINERAL DENSITY IN PATIENTS WITH CHRONIC KIDNEY DISEASE STAGES 3 AND 4

Aristidis Stavroulopoulos 1, Christine J. Porter 1, Simon D. Roe 1, David J. Hosking 2, Michael J.D. Cassidy 1, Nottingham Renal and Transplant Unit; 1Division of Bone and Mineral Metabolism, Nottingham University Hospitals, City Campus, Nottingham, United Kingdom

**Introduction and Aims:** Low vitamin D status is associated with secondary hyperparathyroidism and increased bone turnover in the general population and can aggravate the hyperparathyroidism of chronic kidney disease (CKD) patients. It is also correlated to low bone mineral density (BMD), but this correlation is less clear in CKD patients. Aims of our study were to investigate these associations in CKD stages 3 and 4 patients, and to identify significant predictors of BMD in this population.

**Methods:** Serum 25-hydroxyvitamin D levels (25OHD), BMD at the femoral neck (FN) and radius, and bone mineral metabolism parameters were measured in 89 CKD stages 3 and 4 patients. Patients with prior parathyroidectomy or who had received medication known to affect BMD, 25OHD or parathyroid hormone (iPTH) levels were excluded. Vitamin D status was defined as follows: serum levels between 40 – 75nmol/L= insufficiency, < 40nmol/L= deficiency and < 12nmol/L= severe deficiency.

**Results:** Mean 25OHD levels were 53.8±32.1 mmol/L and correlated to the severity of proteinuria. Thirty-five patients (39%) had vitamin D insufficiency, 29 (33%) had vitamin D deficiency and 5 (6%) severe deficiency. Of the 89 patients, 2 had osteoporosis and 31 had osteopenia either at femur or radius. Thirty-five patients had low vitamin D and iPTH above target for the stage of CKD and should require vitamin D supplementation according to NKF/KDOQI guidelines, but 27 of them had Ca above 2.37 mmol/L, that is the threshold for vitamin D therapy. In the multiple linear regression analysis, independent predictors for the FN T score were the iPTH levels (β=-0.36, P= 0.001) and the body mass index (β= 0.33, P=0.001) for the model: adjusted R²= 0.196, P= 0.001. For the radius T score independent predictor was only the severity of proteinuria (β=-0.28, P= 0.008). Serum 25OHD levels were not directly associated with BMD, but they were independent predictors of iPTH (β= -0.32, P= 0.001), along with the estimated glomerular filtration rate (β= -0.37, P< 0.001) and the Ca levels (β= -0.2, P= 0.024), for the model: adjusted R²= 0.339, P= 0.001.

**Conclusions:** Vitamin D insufficiency and deficiency are very common in CKD stages 3 and 4 population and may indirectly affect (through increase in iPTH), the bone mineral density of these patients. Further studies are needed to examine the impact of correction of vitamin D insufficiency and deficiency on iPTH levels, BMD and fracture risk in CKD population. Limitation of treatment may be the hypercalcemia of these patients, especially if the NKF/KDOQI guidelines are to be followed.

**FP195**  HEPATITIS C VIRUS INFECTION IMPAIRS HEALTH-RELATED QUALITY OF LIFE IN HEMODIALYSIS PATIENTS

Baris Afsar 1, Rengin Elsaser 1, Zubeidey Arat 1, Siren Sezer 1, Bulent Huddam 2, F. Nurhan Ozdemir 1, Mehmet Haberal 2, 1Department of Nephrology, Baskent University Hospital, Ankara, Turkey; 2Department of General Surgery, Baskent University Hospital, Ankara, Turkey

**Introduction and Aims:** Health-related quality of life (HRQOL) is impaired in hemodialysis (HD) patients. Hepatitis C virus (HCV) infection has negative impact on HRQOL in patients with normal renal function. However, HRQOL of HCV positive and negative HD patients was not compared specifically. We compared HRQOL of HCV positive and negative HD patients by using Short Form-36 (SF-36).

**Methods:** Patients performed SF-36 and Beck Depression Inventory (BDI). Hemodialysis dose was evaluated by single-pool Kt/V (spKt/V). Previous transplantation history, economical, marital and educational statuses, presence of coronary artery disease, diabetes and sleep disturbance was noted and laboratory parameters were recorded.

**Results:** Totally 173 patients (male/female: 112/61, age: 49.9±14.2 years, HD duration: 107.1±87.1 months) were included. Eighty-four were HCV positive, 89 were HCV negative. Hemodialysis duration (141.5±68.9 months vs 75.4±47.0 months, p<0.0001), BDI scores (23.1±8.9 vs 23.3±10.1, p= 0.036), aspartate aminotransferase, (19.7±15.0 U/L vs 14.2±7.1 U/L, p= 0.002), alanine aminotransferase, (23.6±24.0 U/L vs 14.3±10.8 U/L, p<0.0001) were higher, low density lipoprotein cholesterol (87.6±31.9 mg/dl vs 101.3±34.0 mg/dl, p=0.007) was lower in HCV positive patients when compared to HCV negative patients. Other biochemical parameters were not different between HCV positive and HCV negative patients. After adjusting for age, HD duration, spKt/V, BDI scores, transplantation history, economical, marital and educational statuses, coronary artery disease, diabetes and sleep disturbances, the results of HRQOL showed that HCV positive patients had worse scores in four subscales of SF-36 namely: general health (36.9±2.1 vs 44.6±2.0, p=0.016), physical functioning (51.4±3.2 vs 64.3±3.0, p=0.007), physical role (34.6±5.5 vs 51.8±4.2, p=0.036) and vitality (38.8±2.4 vs 48.2±2.3, p=0.011) when compared to HCV negative patients.

**Conclusions:** HCV positive hemodialysis patients tended to have higher depression scores than HCV negative patients. HCV infection seemed to have a negative effect on the health related quality of life in hemodialysis patients independently.

**FP196**  RISK FACTORS OF INCREASED ATHEROGENICITY AND WATER OVERLOAD DURING CHRONIC KIDNEY DISEASE PROGRESSION ALSO REFLECT CARDIAC REMODELING

Kyriakos Ioannou 1, Evangelia Doumou 1, Konstantinos Pappas 2, Apostolos Keledis 1, Konstantinos Katopodis 1, Ioannis Tsakiris 1, Nikolaos Kotzadamis 1, Kostas C. Siambopoulus 1, Dimitrios Tsakiris 1, 1Department of Nephrology, General Hospital of Veria, Veria, Greece; 2Department of Nephrology, University of Ioannina, Ioannina, Greece

**Introduction and Aims:** Cardiovascular morbidity is increasing along with the progression of chronic kidney disease (CKD). This is due to the presence of traditional risk factors together with other factors that relate to renal failure itself. The aim of this study was to investigate the behavior of fibrinogen, apolipoprotein-A1 (apo-A1) and brain natriuretic peptide (pro-BNP) in the course of CKD progression and their relation to cardiac changes detected on echocardiogram.

**Methods:** In a cross-sectional observation, a population of 223 steady patients with CKD stages 1 to 4 and a “high-risk” population with normal renal function from the out-patient clinics of two hospitals were studied with echocardiogram and apo-A1, fibrinogen and pro-BNP were measured in 223, 222 and 114 patients respectively and correlated to the echocardiographic findings.

**Results:** Increased fibrinogen levels and decreased levels of apo-A1 are found in atherosclerotic disease. In our study CKD progression was found to correlate positively with an increase in fibrinogen levels (p<0.000) and negatively with the levels of apo-A1 (p=0.005). CKD progression was also found to correlate positively with an increase in pro-BNP levels (p<0.000), probably reflecting the inability of the kidneys to maintain water and sodium balance leading to overload.

Interestingly, all three risk factors correlated also with cardiac changes detected on echocardiogram. Fibrinogen correlated positively with LV mass/BSA (p<0.0000), relative wall thickness (RWT) (p<0.000), intraventricular septum (IVS) (p<0.000) and posterior wall (PW) (p<0.000). Pro-BNP levels also correlated positively with LVmass/BSA (p<0.000), with end-diastolic (p=0.035) and end-systolic diameter of the LV (p=0.025). In contrast, Apo-A1 showed a negative correlation with LVmass/BSA (p=0.02), RWT (p=0.009), IVS (p=0.028) and PW (p=0.001).

**Conclusions:** In conclusion, the increase of fibrinogen levels and the

Epidemiology of CKD I viii5

FP197 ECHOCARDIOGRAPHIC EVIDENCE OF EARLY CARDIAC REMODELING DURING CHRONIC KIDNEY DISEASE PROGRESSION

Kyriaios Ioannou 1, Evangelia Dounousi 1, Konstantinos Pappas 2, Polychronis Christodoulides 1, Apostolos Kelesidis 1, Dimitrios Tsakiris 1, Department of Nephrology, General Hospital of Veria, Veria, Greece; 2Department of Nephrology, University of Ioannina, Ioannina, Greece

Introduction and Aims: The prevalence of cardiovascular disease (CVD) in chronic kidney disease (CKD) has been studied in a series of studies. Up to 80% of people with end-stage renal failure have abnormal echocardiographic findings and this marks a prejudged course of these patients characterized by an increased CV morbidity and mortality. The aim of this study was to investigate the time point in the course of CKD that cardiac remodeling is detectable, so that early interventions will be possible as well as effective in reversing cardiac damage and by this limiting CV risk.

Methods: For this purpose, in a cross-sectional observation 211 steady patients with CKD stages 4 to 5 from the out-patient clinics of two hospitals were studied with echocardiogram. There were 105 males (49.8%) and 106 females (50.2%) and their mean age was 64±12 years old. Primary renal diseases were hypertensive nephrosclerosis 34 (16%), diabetes 30 (14%), interstitial nephritis 23 (11%), glomerulonephritis 19 patients (9%), and in 62 patients (29%) the PRD was unknown. The distribution of the patients in the CKD stages were, CKD 1: n=29 (13.7%) with a mean GFR 118±62 ml/min (Cockcroft), CKD 2: n=55 (26.1%), mean GFR 76±43 ml/min (Cockcroft), CKD 3: n=55 (26.1%), mean GFR 42±8 ml/min and CKD 4: n=44 (20.9%), mean GFR 24±4 ml/min.

Results: CKD progression was found to correlate positively with an increase of left ventricular after adjustment to body surface area LVmass/BSA (stage 1=112 g/m2, stage 2=131 g/m2, stage 3=142 g/m2 and stage 4=169 g/m2, p<0.000). This represented an increase by 17%, 27% and 51% in LVmass/BSA in stage 2, 3 and 4 respectively from stage 1. Significant increase as CKD was progressed was also observed in relative wall thickness (p=0.007), intraventricular septum (p=0.023), posterior wall (p=0.006) and in left ventricular end-diastolic diameter (p=0.031). In contrast, ejection fraction, fraction shortation and LVESD did not correlate significantly with CKD progression.

Conclusions: In conclusion, the progression of CKD stages was followed by a significant remodeling of the heart geometry. Therefore, the well-established cardiac burden and cardiac remodeling in CKD seems to be a progressive procedure starting from the early stages. These findings should prompt early detection as well as proper interventions from the very early stages of CKD when the structural changes in heart geometry are still subclinical and probably reversible.

FP198 PREVALENCE AND CROSS-SECTIONAL ASSOCIATIONS OF A REDUCED ESTIMATED GLOMERULAR FILTRATION RATE IN THE OVER-75 YEAR OLDS

Dorothea Nitsch 1, Paul J. Rodenick 2, Richard Atkins 1, Laim Smeeth 1, Richard Hubbard 1, Chris Bulipit 1, Astrid Fletcher 1, 1Department of Epidemiology and Population Health, London School of Hygiene & Tropical Medicine, London, United Kingdom; 2Applied Epidemiology Group, University of Southampton, Southampton, United Kingdom; 3Department of Clinical Epidemiology, University of Nottingham, Nottingham, United Kingdom; 4Care of the Elderly, Hammersmith Campus, Imperial College, London, United Kingdom

Introduction and Aims: Chronic kidney disease (CKD) can be classified by reduction in the estimated glomerular filtration rate (eGFR). Because the glomerular filtration rate decreases with age, the clinical significance of reduced eGFR in older people is uncertain. The aims of this study were to assess the frequency of CKD in people aged 75 and above, and to evaluate the associations of different levels of eGFR with morbidity and functional status.

Methods: Cross sectional study of people aged 75 and over participating in a cluster randomised trial of health and social assessment of older people in the community between 1994-8 in the UK. There were 13109 (87%) participants in 53 general practices who had a serum creatinine measured in local laboratories at baseline. eGFR was derived from the Modification of Diet in Renal Disease formula (MDRD). Prevalence of different CKD stages was calculated stratified by age and gender. Multiple logistic regression was performed to test for associations with morbidity and functional status adjusting for age and gender.

Results: Prevalence of CKD for eGFR <60 was 56.1% (95% CI 55.3- 57.0%), for eGFR <45 17.7% (95% CI 17.1-18.4%), and for eGFR <30 2.7% (95% CI 2.4-2.9). Prevalence of all stages of CKD was higher in older groups, females, and those with cardiovascular co-morbidity and diagnosed hypertension but not diabetes. The associations with measures of morbidity and functional impairment increased as eGFR fell, especially once eGFR was <45. For example the odds ratios in females for anaemia for eGFR <30 and 30-44 and 45-59 vs reference GFR >60 were 5.69 (4.00-8.12), 1.51 (1.12-2.02) and 1.10 (0.87-4.41) respectively; similar figures for falls at home and poor physical activity were 1.50 (1.03-2.19) and 2.84 (2.16-3.74), 1.36 (1.14-1.62) and 1.38 (1.17-1.62), 1.06 (0.90-1.26) and 1.00 (0.87-1.16) respectively.

Conclusions: Stage 3-5 CKD is very common in older people. An eGFR below 45 identifies a smaller sub-group of older people who are more likely to have significant comorbidity, impaired functional state, and potentially reversible consequences such as anaemia. The benefits of identifying older people with eGFR <45 need to be determined.
LEFT VENTRICULAR HYPERTROPHY IN PREDIALYSIS CHRONIC KIDNEY DISEASE: IMPACT OF CARDIOVASCULAR BIOMARKERS

Tononori Kimura1, Ken-ichiro Ito1,2, Yoshitsugu Ohi1, Terumasa Hayashi1, 1(Nephrology, Rinka General Medical Center, Izumisano Municipal Hospital, Izumisano, Osaka, Japan; 2Geriatric and Nephrology, Osaka University School of Medicine, Suita, Osaka, Japan

Introduction and Aims: Cardiovascular disease is a major cause of death in patients with advanced stages of chronic kidney disease (CKD), including dialysis patients. Left ventricular hypertrophy (LVH) is an independent predictor of mortality and morbidity in patients with end-stage renal disease and is present in over 70% of patients commencing dialysis. However, only a few studies of LVH are available about the patients before the start of dialysis treatment. The purpose of this study is to evaluate the prevalence and clinical correlates of LVH in patients with advanced stages of CKD.

Methods: We performed a cross-sectional study of 92 patients (48 men; mean age 64±9 (34-87) years) with renal diseases but history of neither cardiovascular diseases nor arrhythmia. The mean creatinine clearance was 19.3±8.0 mL/min. We calculated left ventricular mass index (LVMi) using the American Society of Echocardiography cube formula method regressed to anatomic validation. LVH was defined as LVMi greater than 131g/m2 in men and greater than 100g/m2 in women. Circulating levels of human atrial natriuretic peptide (hANP) was measured as a cardiovascular biomarker.

Results: LVH was present in 54% of the population studied. The prevalence of LVH was significantly increased with progression of renal decline: 21% in stage 3, 40% in stage 4, and 71% in stage 5 (P < 0.001). Univariate analyses revealed that creatinine clearance, hemoglobin, systolic blood pressure hANP, and intact PTH (P < 0.01). Stepwise logistic regression analysis demonstrated that hANP is selected as the independent risk factor.

Conclusions: LVH is highly prevalent in patients with advanced stages of CKD, which is associated with severity of renal impairment. hANP is identified as a modifiable factor as predictor of LVH. We suggest that strict control of body fluid could prevent the progression of LVH, and as a result, could attenuate the risk of cardiovascular events in CKD.

DETECTION OF CHRONIC KIDNEY DISEASE IN “HEALTHY” ELDERLY PEOPLE

David Nava, Fabiola Martin del Campo, Susan Ordaz, Liliana Gonzalez, Laura Cortes-Sanabria, Enrique Rojas-Campos, Hector Martinez-Ramirez, Alfonso Cueto-Manzano, Unidad de Investigación Médica en Enfermedades Renales, Hospital de Especialidades, CMNO, IMSS, Guadalajara, Jalisco, Mexico

Introduction and Aims: Renal function physiologically decreases with age; on the other hand, elderly population is increasing dramatically among ESRD patients. Frequently, a reduced renal function in the elderly is attributed to normal ageing, and other causes are not investigated; thus, an good opportunity to identify and treat renal disease at early stages is lost. Few renal function data in apparently healthy elderly people have been published. Therefore, the aim of this study was to determine the prevalence and presence of renal disease risk factors in people older than 60 years otherwise considered as healthy.

Methods: We included subjects older than 60 years, considered as “healthy” and assisting to a program to prevent chronic diseases (PREVENIMSS) in an asymptomatic for heart disease. The presence of LVH was defined as LVMi greater than 131g/m2 in men and greater than 100g/m2 in women. Circulating levels of human atrial natriuretic peptide (hANP) was measured as a cardiovascular biomarker.

Prevalence of LVH was present in 54% of the population studied. The prevalence of LVH was significantly increased with progression of renal decline: 21% in stage 3, 40% in stage 4, and 71% in stage 5 (P < 0.001). Univariate analyses revealed that creatinine clearance, hemoglobin, systolic blood pressure hANP, and intact PTH (P < 0.01). Stepwise logistic regression analysis demonstrated that hANP is selected as the independent risk factor.

Conclusions: LVH is highly prevalent in patients with advanced stages of CKD, which is associated with severity of renal impairment. hANP is identified as a modifiable factor as predictor of LVH. We suggest that strict control of body fluid could prevent the progression of LVH, and as a result, could attenuate the risk of cardiovascular events in CKD.

PRESENCE AND RISK FACTORS OF CORONARY ARTERY CALCIFICATION IN PATIENTS WITH AND WITHOUT DIABETES AND CHRONIC KIDNEY DISEASE STAGES 3 AND 4

Aristides Stavroulopoulos1, Christine J. Porter1, Michael J.D. Cassidy1, David J. Hosking2, Kate Pointon3, Simon D. Roe1, Nottingham Renal and Transplant Unit; 2Division of Bone and Mineral Metabolism; 3Radiology Department, Nottingham University Hospitals, City Campus, Nottingham, United Kingdom

Introduction and Aims: In the general population the prevalence and extent of coronary artery calcification (CAC) have been reported extremely high CAC prevalence with CAC scores up to ten times higher than expected for age and sex. The presence of diabetes seems to increase the risk of CAC, however to date no direct comparisons have been reported between CKD patients with and without diabetes. Aim of this study was to describe the prevalence and extent of CAC in CKD stages 3 and 4 patients comparing patients with and without diabetes and identify risk factors. Another aim of the study was to determine if the presence of peripheral artery calcification (PAC) would assist in identifying patients positive for CAC.

Methods: A cross-sectional study was carried out in 112 patients of both sexes, aged between 18-65 years with CKD stages 3 and 4, 54 with and 58 without diabetes, all asymptomatic for heart disease. CAC was detected by multi-slice computed tomography (MSCT), and PAC by plain foot radiography. Demographic and laboratory data were also collected and analysed.

Results: Prevalence of CAC was 74% and 46.5% in CKD patients with and without diabetes respectively (40/54 vs. 27/58, P=0.003) and the two groups were matched for age and sex. In the multivariate analysis for the whole group, age, diabetes and obesity were the major predictors of CAC. Patients with diabetes had higher CAC scores (159 (1-4074) vs. 47 (2-1196), P=0.002), with more vessels affected [3 (1-5) vs. 2 (1-5), P=0.03], and in the presence of diabetes men and women had the same risk for CAC. Severity of renal dysfunction was a predictor of CAC in the
patients without diabetes, but not when diabetes was present. Smoking was associated with the extent of CAC, especially in patients with diabetes. Phosphate levels were predictive of CAC in patients without diabetes, and parathyroid hormone levels were associated with the extent of CAC in the non-diabetic population and when all CKD patients were considered.

The presence of PAC on plain radiography identified patients with CAC on MSCT, with a sensitivity of 73%, a specificity of 28%, a positive predictive value of 44% and a negative predictive value of 76% indicating that it was not an adequate alternative screening marker for identifying patients with CAC.

Conclusions: CAC is common in CKD stages 3 and 4 patients, especially in those with diabetes. Further studies are needed to establish if lifestyle modifications (smoking cessation and weight management) and therapeutic strategies targeting iPTH and phosphate, can affect the prevalence and severity of CAC, delay its progression and finally reduce the very high cardiovascular disease risk seen in CKD patients.

FP203 FACTORS INFLUENCING EXERCISE PROTEINURIA IN YOUNG HEALTHY PERSONS

Dominka Partycka, Magdalena Leszczynska, Zazanna Ejsmont, Anna Rozumko, Agnieszka Sendrowicz, Marta Kozuchowska, Marcin Zietkiewicz, Dominik Swieton, Wojciech Wolyniec, Boleslaw Rutkowski. Department of Nephrology, Transplantology and Internal Medicine, Medical University of Gdansk, Gdansk, Poland

Introduction and Aims: The intensive physical activity is known as a cause of benign proteinuria. Although in the literature exist some studies describing exercise proteinuria (EP) the explanation of this phenomenon is not fully explained. The aim of the study was to estimate frequency of EP among healthy young participants of long distance march.

Methods: 115 participants of March on Orientation “Harpagan”, all apaceurs, who took at least 50-km walk in the forest have performed urinanalysis with test strips.

Results: 1. EP was found in 26 persons (22.6%), in all cases values reaching 30mg/dl. 2. There was no correlation between presence of EP and age of participants and durations of exercise. Specific gravity (SG) and pH of urine, as well as frequency of erytrocyturia and bilirubinuria were similar in both groups. Ketonuria was more frequent in participants with EP, but differences were not statistically significant. 3. Frequency of EP was lower in participants with ketonuria than in those without ketonuria. 4. Frequency of proteinuria was higher in participants with ketonuria than in those without ketonuria.

Conclusions: Some interesting conclusions can be drawn from this very simple study. 1. After long exhausting march proteinuria occurs only in 20% of young healthy persons. 2. EP is always at minimal range (30mg/dl). 3. Presence of EP is not correlated with duration of exercise but rather with improper diet and may be improper training.

FP204 THE RELATION BETWEEN INSULIN RESISTANCE AND ANTHROPOMETRIC VALUES IN NONDIABETIC HAEMODIALYSIS PATIENTS

Evup Koc, Fatma Ayerdem Ebinc, Ruya Mutlay, Kadiyre Altok Reis, Ulver Boztepe Denici, Yasemin Erten, Arinsoy Turgay, Aydan Yulksel. Department of Nephrology, Gaz University School of Medicine, Ankara, Turkey

Introduction and Aims: It has been known the role of hyperinsulinemia in inflammatory process and its association with anthropometric measurements. We aimed to identify that in nondiabetic haemodialysis (HD) patients, which anthropometric values are related most closely to insulin resistance (IR).

Methods: Five-two nondiabetic HD patients aged 47±14 (22-75) were enrolled. Each subject’s weight, height, waist, hip and arm circumference, biceps and triceps skin fold were measured; body mass index (BMI) and wrist to hip ratio were calculated. Percentage of body fat was analyzed by bioelectrical impedance. In fasting blood samples, complete blood count, insulin, glucose, uric acid, albumin, transferrin, ferritin, HsCRP were measured. IR was calculated by homeostasis model assessment (HOMA) and cut-off point was accepted 2.7.

Results: Of all patients 14 (26.9%) were female, 38 (73.1%) were male. Mean duration of HD was 59.1±42.9 month (2-170), 13 (25.5%) patients had overweight and obesity (BMI >25 kg/m²), 16 (30.8%) had increased body fat (female ≥33%, male ≥22%), 22 (42.3%) had IR. Serum level of insulin and HOMA index were significantly correlated with BMI (r=0.32, p=0.023; r=0.28, p=0.048), respectively and arm circumference (r=0.32, p=0.024; r=0.28, p=0.046, respectively). Hip circumference was only associated with the level of insulin (r=0.32, p=0.029).

Other anthropometric measurements did not relate to insulin level and HOMA index, BMI, hip and arm circumference in patients with IR were significantly more than the other (p=0.031, p=0.008, p=0.037; respectively). Lymphocyte count in this group was less (p=0.036). The levels of uric acid, albumin, transferrin, ferritin and HsCRP did not differ between groups.

The correlation between anthropometric measurements with serum insulin level and HOMA index

HOMA: Homeostasis model assessment.

Conclusions: Regarding IR, in nondiabetic HD patients, BMI and arm circumference are more important anthropometric measurements.

FP205 ULTRASONOGRAPHIC RENAL DIMENSIONAL PARAMETERS HELP PREDICT RENAL OUTCOME IN PATIENTS WITH CHRONIC RENAL INSUFFICIENCY

Domenico Mancuso, Nicolo Comi, Michele Andreucci, Cinzia Donato, Pierangelo Presta, Giorgio Puiano. Nephrology, University Magna Graecia, Catanzaro, Italy

Introduction and Aims: Ultrasonography (US) of the kidney and urinary tract has become the primary modality for the evaluation of urinary diseases since number, location, size and shape of the kidneys, and the collecting system are accurately assessed. It has been shown that renal length and volume are correlated with age and body weight (BW), so that a variability of 5% is present in adults. Since renal length, volume and echogenicity are considered potential surrogate markers of single kidney function, US has been proposed as a screening modality to evaluate patients with chronic renal insufficiency (CRIpts). However, as yet, no study has specifically evaluated the correlation between renal US parameters and GFR levels when age, BW, IP and other parameters supposed to be correlated to GFR are simultaneously considered.

Epidemiology of CKD
Methods: Aim of the study is to verify the relationship between renal US and functional parameters in CRpts (135 pts, stage 2-4 KDOQI) and in a control population (C: 315 healthy volunteers from the staff of two local hospitals). The same sample was evaluated after a two-year follow-up.

Results: Basal study. Mean age was 49.8±13 years, 47.22% male. Arterial hypertension was found in 63.7% of CRI pts and in none of C. Mean serum creatinine was 1.11 mg/dL in C group (range 0.67-1.23) and 3.75 mg/dL in CRF group (range 1.8-7.7). As compared to C, CRI pts presented significantly reduced the renal longitudinal diameter and volume in all CRI stages, while the transversal diameter and cortical thickness were significantly reduced only in pts with stage 3 and 4.

Follow-up. Observation lasted 24±2 months. CRF pts were divided in 4 quartiles according to their basal renal volume. In CRF group 23 pts presented 1 or 2 event failure (reduction >30% of basal GFR and/or start of hemodialysis) and 14 died (3 of these had started RDT). The relationship between these events and clinical, laboratory and US parameters was evaluated by calculating the hazard ratio for unit increase. Reduction of cortical thickness (in III and IV quartiles) and kidney volume (in all quartiles) were identified as risk-factors, as well as the increases in SBP (in all quartiles), DBP (in IV quartile), CaXp product, PTH (in III and IV quartiles), CRP and daily proteinuria in all quartiles. By contrast, normal serum albumine and Hb levels were identified as protective factors. By multivariate analysis, we showed that the every 10 cm³ of kidney volume reduction there is an increase of 18% of risk-events in C vs 38% in CRF pts. The reduction of cortical thickness increases the risk of events by 2% in C vs 21% in CRF patients. Both the risk of progression to ESRD and death were inversely related to the kidney volume (p<0.001 for both the events) at baseline.

Conclusions: Our data establish important correlation of US dimensional parameters with decline-rate of GFR and other non- or traditional risk factors in course of CRI. The simultaneous combination of morpho-dimensional and functional parameters could help to improve the accuracy of the follow-up in patients with CRI with possible therapeutical and prognostic implications.

FP206 RENAL INSUFFICIENCY IN BONE METASTASIS CANCER PATIENTS: PREVALENCE AND IMPLICATIONS ON ANTICANCER DRUGS MANAGEMENT. SUBGROUP ANALYSIS OF THE IRMA STUDY

Vincent Launay-Vacher 1, Stéphane-Oudard 1, Nicolas Janus 2, Christophe Le Tourneau 3, Olivier Risc 2, Xavier Postats 2, Joseph Gligorov 2, Philippe Beuzeboc 2, Jean-François Moreire 2, Gilbert Deray 2,1, Nephrology, Hôpital Européen Georges Pompidou, Paris, France; 2Medical Oncology, Hôpital Européen Georges Pompidou, Paris, France; 3Medical Oncology, Institut Curie, Paris, France; 4Medical Oncology, Hôpital Pitié-Salpêtrière, Paris, France; 5Pharmacy, Hôpital Trousseau, Tours, France; 6Medical Oncology, Hôpital Tenon, Paris, France; 7Medical Oncology, Hôpital Avicenne, Bobigny, France

Introduction and Aims: The IRMA study reported the high prevalence of renal insufficiency (RI) in 4684 solid tumour patients, with a glomerular filtration rate (GFR) <90 mL/min for 50-60%. Furthermore, 80.1% were receiving nephrotoxic anticancer drugs and 79.9% drugs necessitating dosage adjustment. We present the results for IRMA patients with bone metastasis (BM).

Methods: Subgroup analysis of IRMA patients with BM. Data collected: sex, age, weight, serum creatinine (SCr), bone metastasis (BM) and anticancer drugs. The prevalence of SCR>110 μmol/L was assessed. GFR was estimated with Cockcroft-Gault (CG) and abbreviated MDRD (aMDRD) formulae. Drugs necessitating dosage adjustment and those potentially nephrotoxic were identified. Chi-square test was used to compare the prevalence of RI between patients with BM and patients without, for all patients and for breast cancer (BC) ones.

Results: 1000 patients (BC 577) with BM were included: median age 60, mean 59.8, weight 66 kg, 659 women. The prevalence of SCR>110 μmol/L was 8.3%. That of GFR<90 mL/min was 57.9% with CG and 54.7% with aMDRD. 83.4% of treated patients received at least one drug needing dosage adjustment (or no data) and 69% received at least one nephrotoxic drug. The prevalence of RI was not statistically different between patients with or without BM. However, the prevalence of RI was significantly higher in BC patients with BM as compared to BC patients without BM (62.1 versus 56.7%, p=0.04).

Conclusions: RI is highly frequent in cancer patients with BM. Appropriate evaluation of renal function necessitates CG or aMDRD calculation. In those patients, and especially in breast cancer patients with BM, anticancer drugs should be cautiously selected regarding their potential renal toxicity and need for dosage adjustment.

FP207 BIOPSY IN OLDER PATIENTS. IS IT RECOMMENDED?

Rosa Ramos, Luis Carreras, Carlota González, Rafael Poveda, Josep M. Grinyó, Nephrology, Hospital de Bellvitge, L’Hospitalet, Barcelona, Spain

Introduction and Aims: During the last three decade (1974-2004), the percentage of patients older than 65 years who have been diagnosed by renal biopsy have increased progressively: 1974-1984: 6.8%; 1984-1194: 19.49%; 1994-2204: 24.78%.

Methods: In this period of time we have performed 1922 renal biopsies of native kidney in our centre.

Results: 60.5% Male/39.5% Female.320 patients (16.6%) were equal or older than 65 years (group A). 1602 (83.36%) were younger than 65 years (group B). Kidney biopsy in group A were taking in 39% because of nephrotic syndrome, in 33% due to rapidly renal insufficiency and in 11% due to nephrotic proteinuria range. In group B were significantly lower (17.7%;3.35%;17.3%). The final diagnosis is showed on table 1.

Conclusions: Age of patients is cause of worsening renal function and also is accompanied of higher incidence secondary nephropathies. A high number of this secondary nephropathy could be treated effectively, for this reason we believe that renal biopsy must be performed even in older patients.

FP208 CARDIOVASCULAR IMPLICATIONS OF COMMUNITY BASED DETECTION OF REDUCED GFR

Carmen Bernis 1, Amelia Gonzalez-Gamarra 2, Sergio Ruiz-Alonso 2, Ana Diaz 3, Yolanda Hernandez 1, Jose Antonio Sanchez-Tomero 1, 1Nephrology, Hospital Universitario La Princesa, Madrid, Spain; 2Primary Healthcare, Area II Madrid, Madrid, Spain; 3Biochemistry, Hospital Universitario de la Princesa, Madrid, Spain

Introduction and Aims: Chronic kidney disease is an asymptomatic condition managed by primary care physicians. We think that the use of Primary Healthcare Information System (OMI –AP, Stacks, Madrid community) and outpatients’ laboratory database to identify people with low GFR may be an effective strategy to prevent kidney disease and cardiovascular complications.

Methods: We studied in the sanitary area 2 of Madrid community a population of 64481 people older than 14 years, (48664 younger than 85 and 15.817 older than 65) corresponding to 3 primary care centres.
Primary care database records were used to identify age, gender and clinical features of people who had creatinina measurement, between April 2004 and April 2006, performed in the hospital area laboratory as outpatients. The laboratory used the modified kinetic Jaffe assay with coefficient of variation of <3%. GFR was calculated by the abbreviated MDRD formula GFR ml/min/1.73 (Manjunath Curr Opin Nephrol Hypertens 2001).

Results: We found 33.662 creatinina test performed in 19059 different adults or 29% of the population. The proportion of the population with renal testing increased with age; it was 47.2% of those older than 65yr and 23.8% of patients younger. 10.093 patients, 15.2% of the entire population and 52.8% of those with test performed had Ccr between 60 and 90ml/min; 2824, 4.25% of population and 11.8% of tested had Ccr <60. Considering older than 65yr we found 28% of population and 59.4% of those with test performed with Ccr 60-90ml/min; 12.2% (25.6%) with Ccr <60.

The incidence of cardiovascular complications was higher in the group with Ccr<60: 65.1 %HTA, 15.4% diabetics, 11.5 ischemic cardiopathy, 7.4% stroke, 5.8% 28.8%, 8.8%, 4.02% 2.2% in group with Ccr >60 (p<0.05).

Conclusions: Identifying individuals with reduced a GFR using laboratory charts, all medicationsand laboratory measurements. The prevalence of ADR, types (Edwards&Aronson classification), causality (Naranjo index) and severity of ADR, length of hospital stay, avoidability, and outcome were evaluated.

Policitic: Patients were 58.0 (range 18-81) years old, had 4.8±1.2 0.2 comorbid conditions, were taking 5.9±0.1 medications, 52.47% had renal insufficiency. Among 223 inpatients, we found 17.04% with ADR; incidence – 197.3%, 70.45% were determined to be Type A, 25% - Type B and 2.72% - Type C and D according to Edwards&Aronson. 55.16% (n=21) of patients with ADR had CRI (4 patients – I degree; 7 – II degree; 10 – III degree). Five severe ADRs were detected; all were occurred in patients with CRI; 4 in hemodialysis patients.

Conclusions: The number of ADRs experienced by patients with renal insufficiency was not significantly greater than by patients without CRI, but ADRs were more severe. Most ADRs were predictable and possibly avoidable, considering the degree of CRI and co-morbidity; pharmacokinetics and nephrotoxity of drugs; limitation of polypharmacy.

FP210 RENAL INSUFFICIENCY AS A RISK FACTOR FOR DEVELOPMENT OF ADVERSE DRUG REACTIONS
Galya Stavreva1, Dobromir Dossev2, Vasil Todorov2, Russi Marov1.
1Pharmacology and Clinical Pharmacology, Medical University, Pleven, Bulgaria; 2Nephrology and Hemodialysis, University Hospital, Pleven, Bulgaria

Introduction and Aims: Adverse drug reactions (ADRs) cause significant patient morbidity, mortality, and costs. Patients with chronic renal insufficiency (CRI), including hemodialysis patients are at high risk for ADRs and drug-drug interactions. The frequency of ADRs increases with number of medications need, the age of the patient, the number of comorbid conditions and the degree of renal dysfunction.

A 3-month prospective pharmacovigilance study was managed in Clinic of Nephrology and Hemodialysis among hospitalized patients to: (i) detect ADRs as cause of admissions and manifested during hospital stay; (ii) study characteristics of ADRs; (iii) assess the importance of CRI as a risk factor.

Methods: All suspected ADRs were collected by clinical pharmacologist and nephrologists via everyday patient examination, review the patient charts, all medicationsand laboratory measurements. The prevalence of ADR, types (Edwards&Aronson classification), causality (Naranjo index) and severity of ADR, length of hospital stay, avoidability, and outcome were evaluated.

Conclusions: The number of ADRs experienced by patients with renal insufficiency was not significantly greater than by patients without CRI, but ADRs were more severe. Most ADRs were predictable and possibly avoidable, considering the degree of CRI and co-morbidity; pharmacokinetics and nephrotoxity of drugs; limitation of polypharmacy.
Conclusions: Together with other known variables, PTH is an independent risk factor of coronary calcifications.

**FP212 NATIONAL RENAL HEALTHCARE PROGRAM IN URUGUAY**

Laura Soló 1, Emma Schwedt 1, Pablo Ríos 1, 2, Nelson Mazzuchi 1, 1 Renal Healthcare Committee, Montevideo, Uruguay; 2 Renal Healthcare, National Fund of Resources, Montevideo, Uruguay

**Introduction and Aims:** Uruguay is a developing country with an established program (PR) for renal replacement therapy (RRT) for all patients (Pt) with end stage renal disease (ESRD) since 1980 (incidence: 149 pnp in 2005). A Pilot PR targeted to the Public assistance population of Montevideo was tried out supported by the Health Ministry and the National Fund of Resources, to guide the feasibility of a National Renal Healthcare Program (NRHP).

**Methods:** Improve Renal Healthcare (RH) in the entire population (POP) by the implementation of a NRHP for public and private assistance system by steps.

**Specific Objectives:**
1. Promote education for RH and healthy lifestyles in the POP
2. Integrate RH into the first level of assistance to promote early detection of CKD and set optimal timing of referral
3. Optimize Pt care in all stages to prevent or delay progression of CKD.
4. Reduce hospitalization in the second level of assistance to promote early detection of at risk POP through education courses and guidelines; c) Plan the ND visits in a reference counter-reference system, depending on CKD stage, and d) Provide the renoprotective drugs.
5. Keep a longitudinal Registry of Pt with eGFR < 60 ml/min/1.73m², proteinuria >300 mg/day or microalbuminuria >30 mg/day in diabetics
6. Reduce drop out with an electronic alarm that informs when a Pt miss an appointment.
7. Derive Stage 4 Pt to a Pre-dialysis Clinic, staffed by a formal multidisciplinary team (ND, Psychiatrist, dietitians, social worker, vascular surgery and nurses) committed to educate, give social and psychological support, and indicate the timely creation of the access for the selected dialysis modality.
8. Sign a contract of agreement between the NFR and the private and public health centers (PHC) teams, and massive diffusion media.

**Results:**
1) Inform the POP about healthy lifestyles and risk factors, through Primary Health Centers (PHC) teams, and massive diffusion media.
2) Integrate the RH in the First Level of assistance: a) designate a nephrologist (ND) to attend 2 hours a week for each 10000 POP aged 20 years and over. The Pt are referred by primary-care physicians (PCPs) directly from the laboratory; b) Train the PCPs, dietitians and nurses on prevention and detection of at risk POP through education courses and guidelines; c) Plan the ND visits in a reference counter-reference system, depending on CKD stage, and d) Provide the renoprotective drugs.
3) Keep a longitudinal Registry of Pt with eGFR < 60 ml/min/1.73m², proteinuria >300 mg/day or microalbuminuria >30 mg/day in diabetics
4) Reduce drop out with an electronic alarm that informs when a Pt miss an appointment.
5) Derive Stage 4 Pt to a Pre-dialysis Clinic, staffed by a formal multidisciplinary team (ND, Psychiatrist, dietitians, social worker, vascular surgery and nurses) committed to educate, give social and psychological support, and indicate the timely creation of the access for the selected dialysis modality.
6) Sign a contract of agreement between the NFR and the private and public health institutions (HCI) progressively. For achieving comparable results it includes the implementation of the standardization of serum creatinine assay in each HCI with the Committee for Standardization and Quality Control (by calibration to an isotope dilution mass spectrometry (IDMS) reference method.

**Conclusions:** The strategic framework of the NRHP has a continuous approach across primary, secondary and tertiary levels of prevention. Its feasibility has been proven by a pilot PR that now allowed the generalization of a NRHP in Uruguay.
